A		Bell, J. Mackintosh,	765
A B C of Iron and steel, new book	435	copper mines in Siberia	765
Accidents caused by missed holes	277	Bellows, E. C.	482
In metallurgical plants	574	Benguet Consolidated	479
Accounting at metal mines	804	Betts, Harold S.	554
Advice to students	629	seasoning, and grading, new book	554
Alaska, future of interior	595	Billingsley, Paul	907
Labor conditions in	847	department of A. C. M. Co.	512
Metal production during 1919	273	Bingham Mines Co., company report	371
Alaska Gold Mines Co., company report	512	Bishop, James A.	371
Alaska Juneau Gold Mining Co., company report	815	Bismuth, magne-tic separation of	379
Electrical equipment	251	Wm. E. Hitchcock and J. R. Pound	379
Aldrich Pump Co.	733	Black Butte ore, flotation of	117
Allen, A. W., Handbook of ore dressing, new book	696	E. G. Stowell and Will H. Corhill	117
Allen, C. A., and Dr. A. L. Murray, Physical exami- nation for hoisting engineers	421	Blacksmith and good drill bits	81
Allis-Chalmers Mfg. Co., Gasoline-engine driven generator sets	361	Blackwood, Charles Keith, obituary	50
Alta, snowslides at	580	Blanford, Thomas	336
American Cyanamid Co.	513	Blasting accidents from missed holes	277
A. I. M. & M. E. meeting	402	Blue-sky laws	204
Meeting at Ajo	93	Ditto	331
American Mining Congress	206	Ditto	181
American mining engineers abroad	854	Bolshivism in Russia	577
American Zinc, Lead & Smelting Co., company report	623	Bols system of Phelps Dodge Corporation	127
Anaconda Copper Mining Co.	887	Books as tools	852
Analysis of magnesite	943	Borzynski, F.	55
Of minerals and ores of rarer elements, new book	69	Ditto, Operation of Case oil-fired assay-furnace	713
W. R. Schoeller and A. R. Powell	69	Bourne, F. J.	297
Anderson, Robert Hay, obituary	246	Bowl-classifier, Dorr	76
Andros, Stephen O., Petroleum handbook, new book	69	Boyle, Emmet D.	905
Anemometers for air	895	Bradley, Bruff & Labarthe	569
Anniversary, our sixtieth	737	Branner, John Caspar	253
Ditto	783	of Brazil, new book	435
Antimony and its uses	299	Brinsmade, R. B.	385
Mining in United States	201	Matehuala, Mexico	35
Apex litigation at Bunker Hill	791	Ditto	85
Argall, Philip	219	British Columbia metal production	242
Arizona metal production during 1919	276	Broadbridge, Walter	295
Oldest copper mine	647	Broken Hill, froth-flotation at	833
Arnold, Ralph	423	Bruhl, Paul T.	333
Asbestos, a Canadian specialty	531	Budget for the Government	33
Ashio smelter in Japan	224	Buffalo Mines, Ltd., company report	289
Ritaro Hirota and Kyoshi Shiga	224	Bullion, discrepancies in weighing	289
A. S. & R. Co. and Bunker Hill company	795	Bunker Hill & Sullivan M. & C. Co., company report	885
Assay maps	453	Bunker Hill enterprise	255
Of platinum	823	Ditto	857
Assaying, volatilization in	458	Ditto	791
Astor, John Jacob	6	Tramway	931
Atascadero	294	Bureau of Mines	36
Aulbach, Adam	189	Director	666
Austin, L. S.	409	Burghardt, Henry D.	624
Judge M. & S. Co.	116	and work at the forge, new book	624
Austin, W. L.	786	Burlingame, Walter E.	624
Ditto	158	in oil-shale	39
Complex ores in California	158	Burma mine	779
Australia, mining industry in	158	Butte, L. W. V. activity at	652
		Miners strike	628
		Strike at	628
		Butte & Superior Mining Co., company report	511
		V. Minerals Separation	180
		By-product coke-ovens of the Granby Consolidated	600
		W. A. Williams	600
B		C	
B. & A. Mining Co. near Gilham, Arkansas	95	Cadmium in the United States	714
Babbitt, Kurnal R., obituary	212	Calculation of furnace charges	195
Backert, A. O.	435	California metal production in 1919	91
Baker, Ray Stannard	886	Charles G. Yale	91
unrest, new book	17	Calkins, F. C.	262
Ball-mills, fine grinding in	363	Calumet & Arizona company	216
Operation	333	Camp Bird, Ltd., company report	250
Practice	221	Campbell, Andrew	177
Practice, some ideas on	333	Canada, mineral production during 1919	571
Bancroft, George J.	212	J. McLeish	571
Bard, Darsie C., obituary	553	Canadian metal production during 1919	100
Barnes-King Development Co., company report	443	Canadian Mining Institute	467
Barreno mine	300	Car dumper description	473
Barrett, Edward P., and John C. Morgan	300	Loading grating	533
laboratory	158	Wm. S. Evans	533
Bathurst, F. H.	57		
Beckett, P. G., reports on Phelps Dodge operations	788		
Beckman, J. W.			

	Page		Page
Carpenter, E. E., Operations of Nevada Wonder Co. during the War	547	Company reports, cont.	
Carson Hill Co. progress	547	Old Dominion Co.	623
Cascade boxes for flotation	837	Portland Gold Mining Co.	511
Case oil-fired assay-furnaces	713	Ray Consolidated Copper Co.	289, 511, 732
Ditto	931	Santa Gertrudis Co.	250
Ditto	857	Shattuck Arizona Copper Co.	623
Ditto	823	Silver King Consolidated Mining Co.	815
Caunt, G. W., and Henry Louis, Traverses tables, new book	621	Superior & Boston Copper Co.	289
Centrifugal fan, theory of	858	Teck Hughes Gold Mines, Ltd.	512
Chatham, C. E., Mine and flotation-plant of American Graphite Co.	567	Tenimkamining Mining Co., Ltd.	511
Chamberlain, Zear J., obituary	508	Tomboy Gold Mines Co.	250
Chapman, Robert Hollister, obituary	171	Tonopah-Belmont Development Co.	885
Chapter in journalism	715	Tonopah Eastern Mining Co.	885
Chemical laboratory		Tonopah Extension Mining Co.	885
John C. Morgan and Edward P. Barrett	300	United Verde Extension Mining Co.	553
Chief Consolidated Mining Co., company report	289, 844	Utah Consolidated Mining Co.	623
Chile-American Association Mining Scholarship		Victoria Copper Mining Co.	512
Editorial	516	Vindicator Consolidated Gold Mining Co.	511
Chile Copper Co., company report	289	Yukon Gold Co.	623
Chino Copper Co., company report	687, 813	Como Consolidated mill	55
Chloride roasting and leaching at plant of the Tintic Milling Co.	603	Complete practical machinist, new book	
Chloridizing processes	259	Joshua Rose	435
Ditto	77, 529	Complex ores in California	786
Christy, John, obituary	728	Ditto	788
Chromite, future in the United States		Ditto	593
Samuel H. Dolbear	645	Ditto	783
Production in 1919	718	Concentrating at Bunker Hill	525
Clawson, Selden I., Chloridizing processes	79	Concerning gold	822
Climax Molybdenum Co.	513	Metal quotations	331
Climbing hills at Pacheco	818	Concrete mine-bulkhead	536
Coal mining		Coniagas Mines, Ltd., company report	289
Problem	401	Consolidated Interstate Callahan Mining Co., company report	732
Production in India	496	Consortium for China	923
Coeur d'Alene, discovery of gold	42	Contract system in mines	667
Coghill, Will H., and E. G. Stowell, Experimental flotation of low-grade quicksilver ore	117	Wage system for miners	497
Coke industry during 1919	873	Contribution to study of flotation	
Coking plant of the Granby Consolidated		H. L. Sulman	14, 47, 122
W. A. Williams	600	Converter practice	198
Colbath, James S., Crowe process	38	O. E. Jager	788
Colburn, Jr., E. A., Mining in narrow stopes	715	Copper and copperas	735
Colby, William E., Geological experts in the courts	930	Exports	657
Collapse of silver	890	Production	24
Color bar	440	Production in Michigan	202
Colorado metal production during 1919	163	Production in United States during 1919	677
Combination method of mine-sampling		Refinery in Russia	617
Fred H. Dakin	519	Stocks	558
Ditto	630	Coreoran, Ray A., obituary	358
Ditto	303	Corporation and the individual	701
Comet smelter	647	Cortez mine to be re-opened	803
Commonwealth Club on engineering activities	717	Cost of opening Seneca mine	279
Company reports:		Plus method, Westinghouse, Church, Kerr & Co.	556
Alaska Gold Mines Co.	512	Cottrell, Frederick G., Editorial	697
Alaska Juneau Gold Mining Co.	815	Cottrell process in Japan	
American Zinc, Lead & Smelting Co.	623	Ritaro Hirota and Kyoshi Shiga	223
Barnes-King Development Co.	553	Condert, Frederick R., letter from Herbert Hoover	423

COST of living, as estimated from the quotations for 96 staples, rose 1.3% in the month ending December 1, thereby bringing the index-number to a level 131% above that which prevailed before the War. It was 6.1% higher than December one year ago, just after the signing of the Armistice. This suggests how little has been done in the way of industrial reconstruction since the major fighting ceased.

BILLS designed to restrict the size of publications are before both houses of Congress. It is proposed by Senator Capper and Congressman Anthony to limit the daily newspaper to 24 pages, the Sunday issues to 36 pages, weekly periodicals to 75 pages, and monthly to 100 pages. Of course, the publishers have protested against anything so ridiculous and have insisted that any restrictions in the consumption of book paper will not remedy the insufficiency of news-print paper. It is natural that the publishers of newspapers should co-operate with the publishers of magazines, but it is a pity that the obvious waste of paper in newspapers, especially the Sunday issues, should prejudice the case of the more serious forms of periodical literature.

SETTLEMENT of our relations with Mexico is becoming more urgent as it is realized how much depends upon the stability of the oil industry in that country. More than 90% of the fuel-oil used on the Atlantic and Gulf coasts, both for bunkering ships and for industrial purposes, comes from the Mexican oil-wells, in which American and British capital and brains have been so largely invested. Of the 60 million barrels produced annually in Mexico, the U. S. Shipping Board has a contract for 21 million barrels, and by the end of the year just begun it will be using at the rate of 40 million barrels per annum. The total consumption of petroleum in the United States is 30 million barrels more than the supply, including both Mexican and domestic oil, leaving that much to be drawn from the reserves of oil that are stored in this country. The Mexican question cannot be shelved everlastingly; it must be faced and solved at no distant date.

'SIXTY-MILE gold dyke in Australia' is the heading of a dispatch in the 'Morning Scream', which proceeds to state that "a 60-mile ridge of gold" has been found near Kalgoorlie and vouchsafes the information that this is "the longest gold-bearing formation ever

found in history", or geography, presumably. This telegram, which must have been concocted under the stress of an excess of mine-pie and wood alcohol somewhere not very far from the press-room of our contemporary, probably refers to the discovery at Hampton Plains, as described in these columns in our issue of November 8. Another fake telegram in the 'Evening Howl' recounts the discovery of rich silver ore in the Premier mine and draws attention to the Salmon River district, in British Columbia, both of which were described in our issue of November 15. Reverting to the 60-mile lode, it is a fact that the outcrop of the Main Reef series on the Rand has been traced for a distance of 55 miles. The present story, however, is more nearly analogous to the report upon a gold vein in Silerna; it was said to be nine miles long, nine feet wide, and assayed 9 ounces per ton, so that if the ore persisted for nine feet only it would yield \$54,000,000. Unfortunately the report was signed by Ah Li.

THE usual proportion of resignations from the staff of the U. S. Geological Survey has increased to an alarming extent during the past year. In his annual report the Director asserts that 77 members, or 17% of the entire technical staff, resigned to accept positions with private corporations, who offer them in every case a considerably larger remuneration. The Director has followed up 29 former cases of this character and finds that whereas the average salary of these men from the Government was \$2271, the average salary at the start in private employment was \$5121, which after two years became \$7804. Apparently the increased number of resignations is due to the decreasing margin between the salaries paid by the Survey and the cost of living. Setting aside sentimental considerations, and looking at the matter as a purely business affair, the Survey offers much to the young man newly graduated with a degree in geology. He is enabled to complete his education in the school of practical experience while earning enough to live comfortably; he gets a variety and breadth of experience such as can seldom be obtained elsewhere; he has the opportunity for building up a valuable acquaintance among influential men actively engaged in the mining industry. We believe that the unique opportunities offered by the Survey are so obviously advantageous that there will never be difficulty in recruiting suitable members for its staff. The problem is not so much to attract the best material as to determine just how much the Survey can afford to pay those who have

developed to mature ability in its service. In many cases only salaries approaching the worth of their expert knowledge in the open market will suffice to hold them at Washington. The work of the Survey is important to the mining industry and we hope that such appropriations may be made by Congress as will enable the Director to maintain his staff.

LAST week the San Francisco section of the Institute had the pleasure of meeting and hearing the president, Mr. Horace V. Winchell, and the secretary, Mr. Bradley Stoughton. It was much the most pleasant of such affairs during recent years. Mr. F. W. Bradley, chairman of the local section, steered the proceedings pleasantly and himself made some interesting observations concerning the status of the engineer in society. Mr. Winchell told the members about his visits to other sections and touched upon the many useful activities of the Institute. He referred to the coal strike and to the intermittency of operations in the bituminous industry, decreasing the working-time of labor and rendering an enormous capital unproductive during a large part of the year. The shipment of coal during winter was another form of waste; he instanced a train of 154 cars of coal that went from Duluth to Butte and encountered weather so cold, accompanied by such delays in travel, that 52 earloads of coal were consumed in the boilers of the locomotives during the journey. He described how the mining profession was co-operating with officials of the Treasury in adjusting the tax-valuation of mining enterprises. Mines pay 250 million dollars as income-tax and 35,000 financial statements from them are now under examination. A licensing law for engineers has been introduced in many States; in numerous instances it has been modified so as to prevent injurious restrictions; in Idaho the law is limited to civil engineers, who are defined as "not military, mining, or metallurgical"—this being a new and amusing definition of an old professional term. Mr. Stoughton's most interesting statement referred to the American Association of Engineers, the young and assertive organization at Chicago. The secretary of the Association, Mr. C. E. Drayer, met the secretaries of the four founder societies in conference at New York on December 8, on which occasion he suggested that as the Association engaged itself chiefly in welfare, not technical, work, it would be well to arrange a plan to avoid rivalry and promote co-operation. He was told, as Mr. Stoughton said, that "co-operation was our middle name", that the new organization was quite welcome to do its share of technical work, but, that, on the other hand, the older societies could not think of abandoning welfare work, which was one of their recognized functions. Mr. Drayer then suggested that the older societies drop their employment agencies, because his organization was attending to that most effectively. On this Mr. Stoughton remarked that while "The Monad", which is the Association's mouth-organ, shows that 2985 men were helped to appointments during the previous three months, whereas the employment offices

of the four older societies had helped 5909 in a similar way during the same period. It was agreed that the secretaries of the societies would co-operate with the secretary of the Association and the meeting ended with expressions of good-will. This is reasonable, but to us it is evident that keen rivalry exists between the new organization and the older ones; nor will it prove injurious; on the contrary, we think that the older institutions will be stirred to new life and greater usefulness. During his term of office Mr. Winchell has proved a most efficient president, devoting a large share of his time to his duties in such a way as to give increased scope and greater purpose to the activities of the Institute. He will be succeeded by Mr. Hoover, who, as president, undoubtedly will bring the profession into a larger measure of national prominence and social usefulness.

AMONG the items of mining news from London we note that the Mysore Gold Mining Company, the parent enterprise of the Kolar goldfield in India, is to make a new issue of capital in order "to initiate a vigorous policy of exploration and development work". This is to be done by creating 610,000 additional shares of 10 shillings each, thereby doubling the existing capital of the company. The management acknowledges the adverse conditions it has had to face during the past four years, which have compelled a curtailment of exploratory work, thereby diminishing the tonnage of ore in reserve. The circular says: "In its long and remarkable history of prosperity, the Mysore mine has from time to time encountered zones of impoverishment which in due course have again given place to high-grade ore. For some time past the deeper levels of the mine have shown a repetition of the variability of quartz reef mining and have been producing ore of lower grade, while the reef has been of less width than in the upper levels." This is a belated acknowledgment of facts known to those who have followed the course of gold mining in the Kolar district; it is a recognition of conditions that should have been faced many years ago. The management and the shareholders of the Indian mines have been fooling themselves for at least five years, if not for ten, with the idea that their mines were not subject to the general experience of impoverishment in depth. In our issue of December 19, 1914, we published an article by the present writer, on 'Persistence of Ore at Kolar', this being an excerpt from a paper read before the Institution of Mining and Metallurgy, in London, in the course of which the general non-persistence of ore was discussed exhaustively. It was pointed out then that the ore in the Mysore and neighboring mines occurred in well-defined shoots having a pitch of about 45° northward. As the Mysore is the most southern of the group of four rich mines, it has not benefited as much as the Champion Reef, for example, by the incoming of ore-shoots pitching into its ground from its southern neighbor. The talk of "zones of impoverishment" is misleading because the simpler and truer explanation is the recurrence of definite shoots pitching regularly at a

high angle, so that the workings in depth pass through alternations of productive and unproductive ground. As no important ore-shoots have been found south of the Mysore property, there is no reason, only a vague hope, for expecting that a vertical extension of the workings will cut new orebodies. The real condition of the mine has been obscured by drawing upon ore held in reserve in the upper workings and by stating the tonnage available without giving either its grade or its distribution; in other words, the depth of the mine in any year has borne no direct relation to the quality of its output. Again, for the *n*th time, the managers of mines are brought to account for failing to recognize a generalization based upon the world-wide experience of mining, namely, that mines eventually become poor in depth as surely as men are enfeebled by age.

Mr. Hoover on National Economics

Everybody ought to read the article entitled 'Some Notes on Industrial Readjustment', by Mr. Herbert Hoover in the 'Saturday Evening Post' of December 27. The paper founded by Benjamin Franklin publishes a good deal of second-rate stuff, and as a journal of opinion it suffers from the fact that it goes to press about a couple of months before it is cut into weekly instalments, but on this occasion it has scored tremendously by giving the public an article of commanding interest written by the man of the hour. In making this pronouncement of economic policy Mr. Hoover has behind him five years of vital contact with international affairs on the largest possible scale, as well as his career as a mining engineer, during which he had to deal at first hand with the employment of labor and capital in many countries. He has the knowledge and the sympathy required to discuss basic problems of economic policy from the American standpoint: for there is no mistaking the fact that he writes in terms of Americanism, not Americanitis, which is only a pitiful provincialism masquerading as patriotism. His chief plank is the social philosophy that has been developed by the United States during its 150 years of progressive life, namely, "an equality of opportunity—an equal chance—to every citizen". In the following summary of Mr. Hoover's article, we shall quote him nearly verbatim, omitting quotation marks only in order not to interrupt attention. Our society is not a stratification of classes, it is a virile mass, stimulated by competition. We have no frozen class distinctions; the assumption of such distinctions between labor, capital, and the public is the expression of a false kind of class consciousness, which threatens to build for us the same kind of foundations as those upon which Europe rocks today. In order to consider industrial problems intelligently we must have not only a social ideal but an understanding of the economic factors that will contribute to that ideal. The economic forces cannot be divorced from the social, for we deal with human beings, not the "economic man" of the old textbooks. The primary purpose of our national policy is to improve the standard of living of all

our people; that standard of living is the direct quotient of the amount of commodities and service that are available for the whole population. The human animal labors under the major impulse of securing for himself a direct share of these commodities and services; his minor impulse is the joy of craftsmanship and the spirit of duty to the community. The infinite variety of hand and brain can find its maximum development only through the stress of competition. The hope of an unusual return is the spur to unusual activity. The illegitimate division of the surplus is the real cause of quarrel, but the surplus is so small a part of our production that it is possible to stifle the increase of capital by over-payment of wages, or to stifle labor by allowing too great a profit to capital; either extreme will ultimately curtail production or savings, and bring misery upon the entire community. The organization of trades-unions is a safeguard for equality of opportunity, and the recognition of the right to combine cannot be separated from the right to bargain collectively; nor can this principle be accepted wholeheartedly without acknowledging the right of the unions to call men skilled in negotiation to assist them in such bargaining. Any form of combination can be perverted for the purpose of dominating the community; if it is used to dictate social and political measures to the community it is violating the foundations of rule by the majority through representative institutions; when it is used to limit the effort of individual workers or to prevent others from working, it is a violation of community rights and a negation of equality of opportunity. The combination of capital is likewise economically sound up to the point where overgrowth leads to such an excess of bureaucracy administration as to cause inefficiency. The moment such combinations begin to dominate the community, either in wages or prices or production, or to check healthy competition, they violate the primary principle of equality of opportunity. One remedy is to extend the anti-trust laws so as to place such super-combinations under government control as soon as their operations pass a certain proportion of the national production. Nationalization of industry fails by destroying the impulses that create efficiency and the initiative that is necessary to improvement. No scheme based upon political appointment has developed an acceptable alternative to competition as a means for selecting men of ability and character. Under government bureaucracy the only safeguard against graft and favoritism is promotion by seniority, which kills initiative and extinguishes the advantage of extra ability. The price we pay for free play of opportunity is an excess of gain to sundry individuals. The atrocity of such gains out of the misery of a nation at war is unbearable. The inheritance, income, and excess-profit taxes tend to a better distribution of wealth, but the use of excess-profit taxes to remedy an unfair distribution, or even for revenue, discourages initiative and stimulates waste, contributing thereby to the high cost of living. Co-operation in production between capital and labor suffers from the increase in the size of industrial units, because this leads

to such specialization and repetition, and such remoteness of contact between manager and men, as to destroy the mutual responsibility that exists in smaller units. Any effort to promote co-operation will fail if it involves the unscrupulous use of piece-work or an attempt to lower wages by scaling down from the most skilled instead of up from the least skilled. On the other hand, if union labor would adopt the idea of maximum effort and skill on the part of each worker, and the sharing of the result with the employer, then the larger part of the friction in obtaining its other objectives—conditions, hours, remuneration—would disappear. Some kinds of speculation are inevitable, but the individual who injects himself into the normal flow of commodities between the stages of distribution is poaching upon the community and returning no service for the toll he takes. So is the gambler on the stock exchange. Finally, until the Government abandons its method of war finance by way of gigantic inflation of credit, and consequent incitement to speculation, there will be little relief from profiteering and its bitter sequel of a high cost of living. We hope that this summary will cause our readers to study the original text and obtain the full benefit of the article, which, as we have said, presents in succinct form an economic policy acceptable to all good citizens. It is worthy of Mr. Hoover's reputation. In the same issue, the editor of the 'Saturday Evening Post' makes an attack on politicians, which may be justified by conditions at Washington, but is couched in terms so blatant and vulgar as to repel even those in agreement with his main argument, which is that we are in urgent need of relief from petty politics. It looks as if the editorial were meant to direct attention to a man of unconventional abilities and free from the faults against which it rails, but we question whether Mr. Hoover wants or needs such advocacy. His acts and utterances speak for themselves.

Let Us Have Peace

The artificial division of time invests the first day of January with sentiment: it serves to punctuate the periods of life, and halt the heedless progression of human thought. It is a day for taking stock of the morrow; whither are we voyaging and how stands the barometer? Let us confess that 1919 has been a great disappointment to the idealist and the optimist, to men of liberal thought and hopeful vision. When the Armistice was signed near the end of 1918 and peace was promised at an early date, we looked to 1919 to redress the disordered balance of the world and to heal the hurts of the great conflict. We looked forward to a period of reconstruction in our country and of rehabilitation in those devastated by war. 1919 failed to fulfill its promise. Much of Europe remains distracted and unorganized, famine and pestilence stalk in the wake of the grim spectre of war, the Russian cesspool corrupts the air of three continents, the treaty of peace is not signed, the covenant of the League of Nations has been rejected, and even the nations that were allied in battle have so lost their feeling of comradeship that they suspect each

other almost as much as their unrepentant foe. It is a miserable ending to a black chapter in human history. Evidently a great mistake was made. The Armistice came too soon. It were better to have continued the fighting long enough to have finished the task of conquering the Germans in battle and then treating them generously, instead of leaving the military task unfinished, so that it had to be supplemented, after the Armistice, by an economic blockade and other reprisals. "The world has had a great fright," as Mr. Lloyd George said, and in its fright it took a number of precautions that reflected the distrust of mankind and the apprehensions of the allied nations so thoroughly as to undermine the foundations for peace. It would have been better, as we see it now, to have finished the War and foregone the demands for punitive justice; to have ended the economic blockade and abstained from penalizing unborn generations; to have made a generous gesture and allowed the Enemy all the help he needed to regain a healthful natural life; to have called for the aid of all, conquered as well as conquerors, in a united effort to bring order out of chaos and economic stability out of internecine strife. The end of the year finds civilized mankind in a mean mood, suspicious, jealous, greedy, and quarrelsome. The message of Bethlehem sounds as foreign as Aramaic; a snarling as from the jungle gives a hideous undertone to current controversy. Only one remedy is evident, and that is to make an end of the existing warfare of mind by concluding a peace such as will hasten a restoration of international relations and thaw the frozen arteries of trade. We are not surprised that a body of men so sagacious as the New York Chamber of Commerce passed a resolution demanding peace, even if "it necessarily involves some sacrifice of long-cherished precedents and practices". They say: "We want it speedily; but we want an honorable peace. Many parts of Europe are in desperate plight. A peace in which we wrap ourselves in the robes of isolation and self-interest would be as dishonorable as further delay would have been in our decision to enter the War on April 6, 1917." It is folly to continue talking, whether at Washington or elsewhere, while the complex organism of civilization is breaking to pieces. We have been warned, by Mr. Hoover and others, of an industrial collapse, at home and abroad, if international trade continues to suffer check by reason of delay in reconstructive work. The present condition of international exchange is eloquent to those who understand its meaning. You can smuggle against an embargo or a tariff, but not against an unfavorable rate of exchange; that kills business with other countries. The failure to conclude peace is not only withholding the essentials of reconstruction from the European peoples, but it is threatening increasingly to congest our production and aggravate the domestic difficulties arising from our recent state of war. The time has passed for sacrificing this great issue to the play of partisan politics; in the name of a common humanity and an enlightened national spirit, let us have peace!

The Bunker Hill Enterprise—I

A Historical Retrospect: The Oregon Territory and Early Exploration

By T. A. RICKARD

The chief lure to exploration in the south and south-west of the American continent was the miner's search for the precious metals; in the north and north-west the trade in furs took the hunter into the primeval wilderness. The Spaniard pushed his conquest into the mountains of the tropics, seeking gold and silver, while the Briton and the Frenchman invaded the Arctic in eager competition for the rich peltries of the snowy regions. It was the fur trade that sustained the earliest Canadian settlements and caused the French to penetrate the vast hinterland to the west of them. They were followed by the agents of British merchants in New York; and after the British colonists south of Canada had won their independence, the American trader joined in the quest, each in turn striving to reach beyond the others into fresh preserves and to do business with the aborigines that roamed over them, until, at least, these westward trails of adventure dipped into the Pacific Ocean.

A few dates will recall the springs of American civilization. Columbus discovered the new world in 1492; Ponce de Leon explored Florida in 1512; Cortez placed his mailed list on Mexico in 1520. All these sailed under the flag of Spain. The fisheries of Newfoundland were exploited by the Bretons and Basques at least as early as 1504¹; Verrazano entered the bay of New York in 1524; Jacques Cartier sailed up the St. Lawrence, as far as the present site of Montreal, in 1534. These were Frenchmen. Henry Cabot made the first landing upon the American mainland in 1497; Raleigh attempted to colonize Virginia in 1585; in 1607 John Smith founded Jamestown; in 1620 the Pilgrims disembarked from the 'Mayflower' on Plymouth rock. These sailed under the English flag, and planted their ideals of liberty on the soil of America.

Some of the first settlers were seeking to escape from tyranny in Europe, but many of the early sailors and explorers who crossed the Atlantic were looking for fabled mines of gold and silver, of which they had heard from the aborigines. After Cortez and Pizarro broke into the natural treasure-vaults of Mexico and Peru the idea of finding metallic wealth in other regions became firmly established. The tales of El Dorado, the gilded man, and of Cibola, the seven cities of untold riches, fevered the imagination of the first European adventurers. The gilded man proved a myth that arose from the swamps of Venezuela, and the seven cities were found at last to be no better than adobe dwellings in the desert

of Arizona. The visions of finding hoards of precious metal had their day in stimulating the pioneers of civilization in the north as well as in the south, but the recognition of the wealth to be derived from the trade in furs in the northern parts of America became general at the close of the 17th century and thenceforward served as a spur to discovery and exploration into the back-ground of the coastal colonies.

Competition in the fur trade at first was unrestricted by treaties or territorial limitations, and culminated therefore, as was to be expected, in disputes that left their mark on the map of North America. I shall attempt a brief review of the history of commercial expansion in the North-West, because upon it was founded the migration on which the country depended for its industrial development², more particularly the development of its mining industry and the eventual discovery of the ore deposit that became the basis of the important mining enterprise to which this series of articles will be devoted.

The earliest curiosity concerning the north-western part of this continent was aroused by the idea of finding a way from Europe to India. The fable of a supposed transcontinental water-way, called the Strait of Anian, enticed the Spanish pioneers northward from Mexico, as the similar tale of a Northwest Passage took the English navigators into the Arctic ice. Cabrillo sailed up the Pacific coast from Mexico to San Diego in 1542; Drake voyaged as far as Vancouver island in 1558; Portola discovered the Bay of San Francisco in 1769; Perez in 1775 went to where Sitka is now; and Cook, in 1778, on his last voyage, reached the Alaskan coast from Hawaii.

The Spaniards established themselves in northern California in 1770, and shortly afterward claimed the entire Pacific coast as their own, but English and Russian fur-trading vessels began to come around Cape Horn in order to barter with the Indians, and the English even made a tentative settlement at Nootka, on Vancouver island. The Russians had discovered Alaska in 1741, when Alexis Chirikoff, sailing from Kamchatka, anchored in Cross Sound, and returned to the Asiatic mainland with a fine assortment of furs. Soon trade was established with the Aleuts, and the *promishlenniki*, or fur-traders, came regularly from Siberia to hunt the sea-

¹'Pioneers of France in the New World', by Francis Parkman.

²It is noteworthy that at this time the fur business, which led to the early development of the Oregon territory, is the liveliest industry in the Yukon and Alaska on account of the appreciation in the value of furs and the depreciation of gold.

offer. In 1783 Shitikoff erected a factory on Kadiak island and in 1799 the Czar Paul gave control of the Alaskan colony to the fur-traders doing business under the name of the Russian-American Company. Conflict between them and the English did not mature until later, but the dispute between Spain and England was adjusted in 1789, when Spain agreed not to extend her claims farther north than latitude 42 N., which is the present northern limit of California. On May 11, 1792, Capt. Robert Gray, commanding the 'Columbia', entered the mouth of a great river in latitude 46 19' north and named it after his gallant ship. The natives thought the ship was a floating island; they feared that the landing crew were cannibals, but, as they were well treated, they proved friendly. On putting out to sea, Gray fell in with Vancouver and told him about the great river, furnishing him with a chart of the entrance. Vancouver explored it, and his lieutenant, Broughton, ascended the river more than a hundred miles, getting a sight of a snowy peak, which he named Mount Hood.

Meanwhile hunters and explorers from the Atlantic seaboard were endeavoring to cross the continent and establish communication with the Pacific coast. The French *voyageurs*, or professional carriers and canoe-men, and their comrades the *coureurs des bois*, or rangers of the woods, were the leaders in penetrating the interior in furtherance of their trade with the Indians. At first the fur trade was conducted chiefly along the lower St. Lawrence and the Saguenay rivers; later, the Ottawa and the Great Lakes proved more productive and made Montreal the great market for furs. In 1615 Champlain reached Lake Huron and Lake Nipissing. In 1670 the Hudson's Bay Company, an English enterprise organized by Prince Rupert and seventeen other nobles and gentlemen, under charter from Charles II, was given exclusive privilege over the back country, and "the Governor and Company of Adventurers of England trading into Hudson's Bay" began their career of commercial expansion westward. The French had broken the furrow, but the British conquest of Canada in 1762 prevented them from reaping their harvest. During the wars between England and France, the agents of the Hudson's Bay Company were much harassed by the attacks made upon their posts by the French, but these depredations ended with the cession of Canada to Great Britain in 1763. The fur business began to attract many, and fierce competition ensued, resulting in the wasting of merchandise and credit in unscrupulous dealings with the natives. The Indians were debauched by the sale of spirituous liquors and their respect for the white man was undermined by bloody feuds between rival parties of fur-hunters, who turned the trade into lawless confusion. To correct some of these evils, the Northwest Fur Company of Montreal was formed in 1787. The agents of this company, like those of the Hudson's Bay Company, were mostly Scots of thrifty habit and hardy physique. Their names are to be found all over the map; the frequent 'Mac' reminding us of the dour forerunners of civilization in the days when the Highlander held

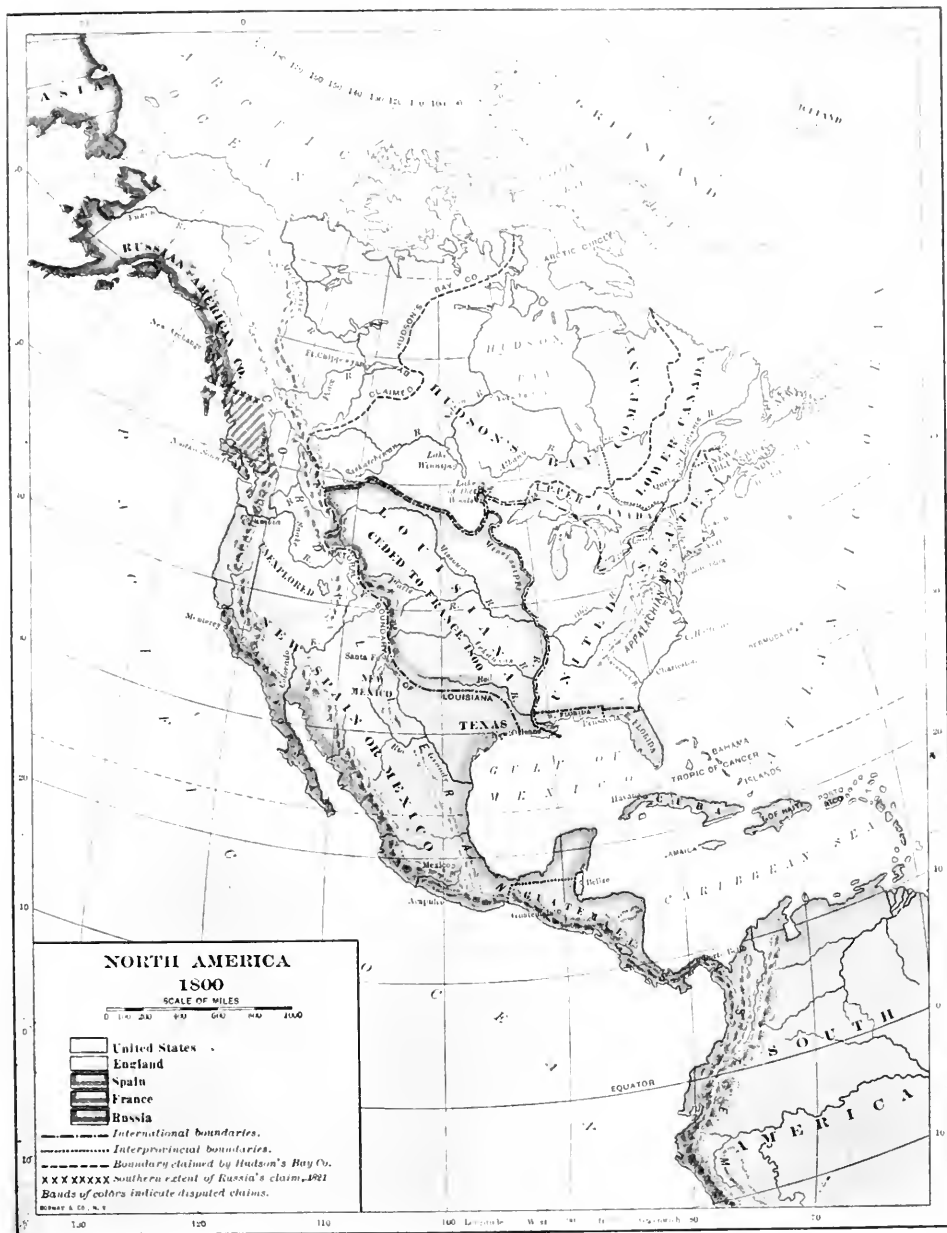

sway over the lakes and forests of western and northern Canada. The reduction of competition to the Hudson's Bay and the Northwest companies served to restore some measure of dignity and decency to the fur trade. The success of these enterprises led to the starting of others, such as the Mackinaw company, which pushed its way south-westward into what is now United States territory.

In 1751 the French explorer De la Vérendrye got as far as the Yellowstone. Many efforts were made to cross the continent: by John Ledyard in 1788, by John Armstrong in 1790, and by André Michaux in 1792. These failed, but on July 22, 1793, an intrepid Scot, Alexander Mackenzie, fortified by experience in north-western exploration and traveling by way of Lake Athabaska, the Peace river, and the Fraser, reached tidewater.

Then others came overland to share in the lucrative trade developed on the Pacific coast. Possession of the region now covered by Oregon, Washington, the southern part of British Columbia, and the northern part of Idaho, was contested by various claimants. By the treaty with France, in 1763, Great Britain had obtained control of the country west of the Mississippi, but the province of Louisiana, held first by Spain and then by France, extended into the vague remoteness of the North-West toward the Columbia watershed. In 1789, as we have seen, Spain limited her claims along the coast to a point 290 miles south of the mouth of that river, for the Spaniards had made no settlement and had obtained no foothold so far north. The Canadian fur companies sent their agents overland to trade with the Indians on the coast, and dealers from New England came in ships, around the Horn, to compete with them. Meanwhile the Russians were extending their trade southward from Alaska, and the Russian-American Company was claiming suzerainty over this *terra nullius*, by virtue of discovery and occupation southward, even below the mouth of the Columbia. In order to finish with the Russian participation in this boundary question, I shall anticipate by saying that in 1823 John Quincy Adams, Secretary of State, boldly controverted the Russian claims and in 1824 a treaty was signed limiting the Russian sphere of influence to north of 54°40'. Thus the Spanish, French, and Russian claims were eliminated, making room for the English-speaking peoples, for after 1783 there were two such peoples, which thereupon became rivals for the possession of 'Oregon', as the watershed of the Columbia was called in those days. See maps No. 1 and No. 2.*

The commercial activities of Canadian companies operating southward were noted by the government of the United States; the leaders of the new American nation looked askance at the growing influence acquired by foreigners over the aboriginal tribes within its own territories; therefore in 1796 an effort to counteract these activities was initiated by the American government and an attempt was made to establish rival trading-posts on the frontier, but unsuccessfully, because "the dull patronage of government failed to outvie the keen activity of

MAP No. 1

private enterprise". What the Government failed to do, the energy and enterprise of an individual succeeded in accomplishing. John Jacob Astor was the man. Astor was born in the German village of Waldorf, near Heidelberg, on the Rhine. He started his commercial career in London*, where he was living at the time of the American Revolution. In 1783 he determined to follow an elder brother, who had been residing in America for several years. The ship on which Astor sailed, together with a stock of merchandise into which he had put his savings, was detained by ice in Chesapeake bay, off Baltimore, and during the three months of inaction he became acquainted with a fellow-German who happened to be a furrier by trade. From him he obtained information concerning a business to which he had already been attracted by what he had heard about it. On arrival at New York, Astor sold his merchandise and invested the proceeds in furs, with which he returned from New York to London in 1784. He disposed of them satisfactorily and came back to New York the same year. Thereupon he devoted himself, perseveringly and thriftily, to his career as a fur-trader. He made visits to Montreal, where he made purchases of furs, shipping them direct from Canada to London, because until 1795 there were many restrictions upon trade between Canada and the United States. Immediately after a treaty had been signed, lifting these restrictions, Astor made a contract with the Northwest company, which established the first posts beyond the Rocky Mountains, north of the Columbia, in 1806. In 1807 Astor embarked in the trade on his own account, ceasing to be merely a broker or middle-man. He had now the capital and resources requisite, but he soon found that despite his knowledge and enterprise he could not overcome the opposition of the Mackinaw company, which controlled most of the trade within American territory. He appealed to the American government for help, offering to turn the whole business of that part of the continent into American channels. His plans were warmly approved at Washington. In 1809 he obtained a charter from the legislature of New York State incorporating the American Fur Company with a capital of \$1,000,000. This capital was furnished by Astor himself; in fact, he constituted the company. In 1811, in conjunction with certain partners of the Northwest company and others engaged in the fur trade, he bought out the Mackinaw company and merged it with the American Fur Company into a new association called the Southwest Company. This was done with the knowledge and approval of the American government. Unluckily the war of 1812 suspended the operations of the new company, and after the war it was dissolved, Congress having passed a law prohibiting British fur-traders from doing business within the territories of the United States.

During the time that Astor was building up his business overland from the Atlantic coast, others were pushing their way by sea, around Cape Horn, for the same

purpose, skirting the north-western rim of the continent from California to Alaska. In 1792 there were 21 vessels under different flags on the coast and trading with the natives. Many of these belonged to merchants of Boston. They would spend two summers on the coast, wintering in the Hawaiian islands,* and then sell their cargo of peltries in China, where they loaded themselves with tea, fabrics, and other merchandise, returning home after an absence of three years. Meanwhile the Russians had established permanent trading-posts on the Alaskan coast and among the Aleutian islands. China was then the great mart for furs and the Russians had the better access to the northern parts, where they were most in demand, whereas their American competitors had to sell at Canton, from which the furs had to be distributed northward. Among the American ships in the fur trade was the 'Columbia', commanded by Captain Gray of Boston, who discovered and named the great river, as we have seen.

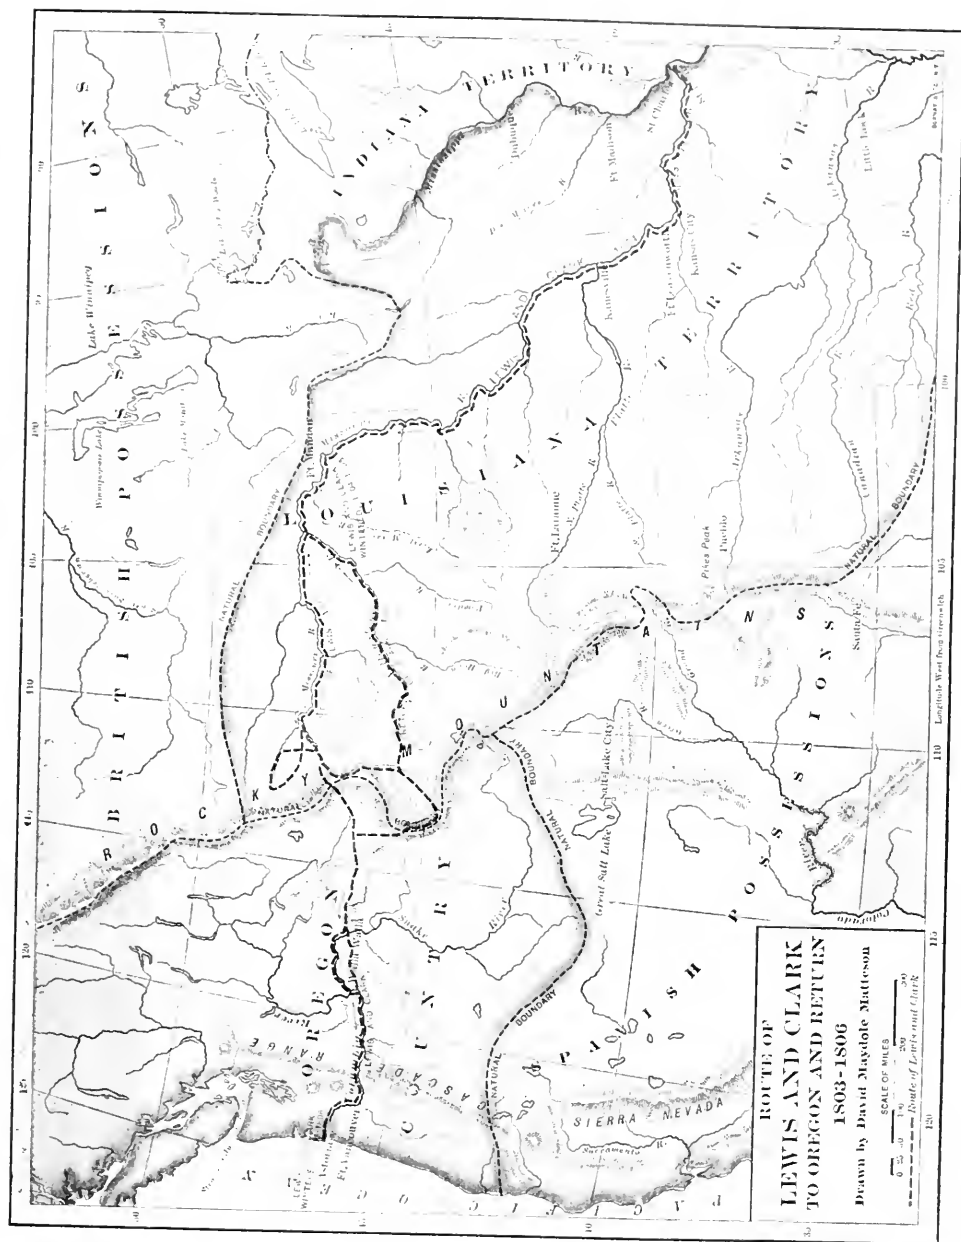

Then came the Louisiana purchase and the Lewis and Clark expedition, to which we must digress, leaving Astor for a while.

In 1803 the purchase of the immense territory called the Province of Louisiana was arranged between Thomas Jefferson, then President of the United States, and Napoleon Bonaparte, then First Consul of France. This central portion of what is now the United States was claimed in 1682 by the explorer La Salle for France, which continued to hold the title to this vast domain until 1762, when it passed by treaty to Spain, only to be ceded back to France in 1802, in consequence of Napoleon's military domination of Spain. Jefferson did not like to see New Orleans and its hinterland passing into the hands of France. Spain did not matter; she was quiet and feeble, whereas France was restless and aggressive under Napoleon, who had dreams of founding a French colonial empire on the American continent. Therefore Jefferson hinted at an alliance with England unless France ceded the region for an equivalent in money. The expression of American feeling that Jefferson elicited came as a surprise to Napoleon, who concluded that a contest was not worth while, for his navy had been shattered by England and it was evident that only maritime supremacy could serve to retain this trans-Atlantic colony; so he resolved to put it out of the grasp of England and at the same time replenish his military chest by selling Louisiana to the United States. The price was 60 million francs. Perhaps he had an idea that when he became master of the world he could compel a retrocession. The completion of the sale was facilitated by the house of Baring, in London, not without the cognizance of the British government, which was quite satisfied to see the transfer of the province from France to the United States. By the terms of this purchase a vast tract of land was added to the national domain; it covered more than a million square miles, or more than the total area of the United States at that time. Not only did it double the territory of the United States, but it gave to the United States indisputably the control of the western hemisphere. Louisiana

*Then known as the Sandwich islands.

included the present States of Louisiana, Arkansas, Missouri, Kansas, Iowa, Nebraska, South Dakota, North Dakota, Wyoming, Montana, Oklahoma, and parts of Minnesota, Colorado, and Idaho; but its limits northward were vague, so that historians do not agree as to the exact portion of country it embraced. For instance, it is not certain how much, if any, of Idaho was included. If it was limited to the watershed of the Mississippi, it would not include Idaho, which is drained by the Snake, the Salmon, and the Spokane, all of which are tributary to the Columbia river. At that time the entire population of this vast region, exclusive of the Indian tribes, consisted of 90,000 persons, of whom 40,000 were negro slaves. The white inhabitants were principally French.

In order to explore and investigate this new domain, President Jefferson, just before the actual transfer (on April 30, 1803), asked the Congress to appropriate \$2500 for an expedition, which was placed under the direction of Capt. Meriwether Lewis,* who chose Capt. William Clark as his chief assistant. This famous Lewis and Clark expedition consisted of 28 men, including the two leaders. Nine of them were young frontiersmen from Kentucky, 14 were soldiers from the U. S. Army, and two were French voyageurs.⁵ At that time the country beyond was quite unknown, weird tales were current concerning it, and when the explorers started to cross from the headwaters of the Missouri to the upper reaches of the then newly discovered Columbia, they were hardly expected to return. To show the vague notions in the mind of Jefferson as to the route likely to be taken on the return journey, it may be noted that in his instructions to Capt. Lewis he said: "Our consuls, Thomas Hewes, at Batavia, in Java, William Buchanan, in the Isles of France and Bourbon, and John Elmslie at the Cape of Good Hope, will be able to supply your necessities by drafts on us."⁶

The party set forth up the Missouri on May 21, 1804. They wintered on the north bank of the river opposite the spot on which years later Fort Clark was established in what is now McLean county, North Dakota. They ascended the Yellowstone and then the Jefferson. In August of the following year they entered what is now Idaho, reaching the junction of the Salmon and Lemhi rivers. In his journal Lewis speaks of the Shoshone Indians. He describes their migratory life, rendered necessary by search for food—salmon in summer and buffalo in winter—and their constant fights with the Pahkees, "the roving Indians of the Sascatchewan". He found them friendly, largely owing to his own considerate treatment of them. "The Shoshones are not only cheerful, but even gay; and their character, which is more interesting than that of any Indians we have seen, has in it much of the dignity of misfortune. In their intercourse with strangers they are frank and communicative; in their dealings they are perfectly fair; nor have we, during our stay with them, had any reason to suspect that

the display of all our new and valuable wealth has tempted them into a single act of dishonesty. While they have generally shared with us the little they possess, they have always abstained from begging anything from us. In their conduct towards us they have been kind and obliging; and though on one occasion they seemed willing to neglect us, yet we scarcely knew how to blame the treatment by which we were to suffer, when we recollected how few civilized chiefs would have hazarded the comforts or the subsistence of their people for the sake of a few strangers."

On August 30, 1805, the expedition started to cross the Bitter Root range. They "pushed on through the trackless wilderness, sometimes traveling on the snow that now covered the mountains". Soon all signs of game disappeared, so that, on September 14, "they were forced to kill a colt, their stock of animal food being exhausted. They pressed on, however, through a savage wilderness, having frequent need to recur to horse-flesh." Some of it was supplied by shooting wild horses, which had strayed from Indian camps. On September 20 the party "descended the last of the Bitter Root range and reached level country. They were at last over the Great Divide." Here they found some hospitable Indians and stayed with them several days. These Indians called themselves Chopunnish, or Pierced Noses, a name now commonly rendered *nez percés*, following the lead of the French voyageurs. However, it is recorded that these people, as far as known, did not pierce their noses. The expedition rested on the Kooskooskie (now the Clearwater) river, near the present site of Pierce City, at one time the county seat of Shoshone, the county in which is the great mine to which this writing is directed. Here they obtained information about the western watershed. The chief, named Twisted Hair, drew a chart of the river on a white elk-skin, explaining the relations of the Clearwater, the Snake, and the Columbia rivers. Having found a place where good timber was abundant, they started the building of boats. On October 8 the party set out in five canoes. They found the river full of rapids, so that progress was limited to 20 miles per day. At the confluence of the Clearwater and the Snake rivers they camped on the site of Lewiston, named after Captain Lewis. From this point they crossed into the present State of Washington. On October 17 they reached the 'Great River', as the Indians called it—the 'River of the North' or the 'Oregon', as the Columbia had been known to earlier explorers. On November 2 they reached tide-water and heard a few words of English from an Indian. In approaching the ocean they were exposed to a heavy storm, which fortunately they escaped by landing on the shore of Baker's bay on November 12. They had completed the crossing of the continent. On December 3 Captain Clark carved on the trunk of a big pine-tree this inscription:

"Wm. Clark December 3D 1805 by land from the U. States in 1804 & 5."

On the return journey, in 1806, they made the crossing of the Bitter Root range with much less trouble, because

⁶Brooks, p. 13.

ASTORIA; GRAIN ELEVATOR AND WARSHIPS

the snow was hard enough to bear their horses and the fallen timber was so covered with snow as to obstruct them less, but the shortage of fodder compelled them to return to camp among their friends the Nez Percés in Quamash flats. On June 26 they made a fresh start and three days later they were out of the snow and fairly on their way into Montana, reaching the present site of Missoula on July 3. Four days later they went through the pass in the Rocky Mountains now named after them. On the plains they found themselves in the midst of great numbers of buffalo, so numerous that they seemed one immense herd. "Hanging on their flanks were wolves; hare and antelope were also abundant." On September 3 they reached St. Louis. "We arrived at 12 o'clock; and having fired a salute, went on shore and received the heartiest and most hospitable welcome from the whole village." So writes Capt. Lewis, who announced his arrival to the President in a letter dated September 23, 1806. Jefferson's reply was dated October 20, the difference in dates suggesting the slowness of the mail service in those days. In his letter the President expressed his "unspeakable joy" at their safe return.⁷ No news had

been received from the explorers for two years and four months. The first post-office in what is now the city of St. Louis was established in 1808 and mails between that "village" and the Atlantic seaboard required six weeks to pass either way.

Let me digress again for a moment. The search for the Northwest Passage yielded much knowledge concerning the navigable rivers of the American continent and opened the eyes of the explorers to the fur resources of the regions that they traversed. The rivers became the natural highways to the interior, and up them went the early colonists, the trapper and the trader leading the advance. Through the middle of the American continent, from the Arctic Ocean to the Gulf of Mexico, there runs

⁷Both these pathfinders were by birth Virginians. Lewis had been private secretary to Jefferson. After his return from the West in 1806, he was appointed Governor of Louisiana. He died by violence, mysteriously, in Tennessee on his way to Washington in 1809. Clark, on his return, was made Brigadier General and agent of Indian affairs. For seven years he was Governor of the Territory of Missouri. He died in 1838, at the age of 68, much respected.

GENERAL VIEW OF ASTORIA AND THE MOUTH OF THE COLUMBIA RIVER

a wide trough, which is crossed by the valley of the Great Lakes, on each side of which there is a low rim that separates the northern from the southern watersheds and the streams that once connected them. Short portages afforded the French voyageurs a method of linking the waterways north of the Great Lakes with those south of them; indeed in times of flood the connection was unbroken. Thus the French fur-traders, by adopting the use of the Indian canoe, paddled along a Canadian river into one of the lakes and across it, southward; then, carrying their boat for ten miles or less, they launched it on a stream that carried them into the tributaries of the Mississippi. The accompanying map shows these portages.⁸ After the Mississippi valley had been entered and colonized, the finger of exploration pointed westward, where the barrier of the Rocky Mountains intervened an imposing barrier to the migration of the people coming from the Atlantic coast. Again a river afforded a way of approach for the trapper and prospector. The Columbia throws mighty arms as far as the headwaters of the Athabasca in the north, and as far as the sources of the Platte and Colorado in the south; it penetrates the heart of the Rocky Mountains and almost touches fingers with streams that feed the Missouri. Lewis and Clark followed the Missouri and then its most westerly branch, the Yellowstone, to the mountain barrier, through which they penetrated by the Indian trail over the Lemhi pass, thereby reaching a branch of the Salmon river, which would have led them to the Snake and thence to the Columbia; but the Salmon was not navigable, so they turned northward over the range until they struck an upper branch of the Clearwater, down which they floated in their canoes first to the Snake and then into the Columbia itself, to the sea.

The movement of population from the eastern seaboard to the regions behind the Alleghanies began before the Declaration of Independence, but the Lewis and Clark expedition was the first to break through the barrier of the Rocky Mountains and start "the winning of the West."

Now we return to Astor. The reports published by Lewis and Clark showed him the practicability of maintaining a line of communication across the continent. He decided to establish trading-posts along the Missouri and the Columbia, with others between. As the mouth of the Columbia he would have his chief establishment and to it he would send a ship each year from New York with supplies and merchandise suited to the trade with the Indians. He submitted his scheme to Jefferson, who gave it his warm approval, because the President foresaw that it would facilitate the spreading of the American people toward the Pacific Coast and thereby promote the growth of the nation. With the approval of the Government, Astor organized two expeditions, one by land, under Wilson Price Hunt, of New Jersey, and another by sea, to go around the Horn to the mouth of the Columbia. For this he provided the 'Tonquin', a ship of 290 tons burden, mounting 10 guns, and with a crew of 20 men. She carried a varied assortment of merchandise, including seeds.

The captain was Jonathan Thorn and with him went Alexander McKay, Duncan McDougal, and David Stuart, these three being former agents of the Northwest company who had been taken into partnership. A number of clerks and artisans, besides 13 Canadian voyageurs, were included in the expedition.

On September 8, 1810, the 'Tonquin' set sail. The ship's company did not behave well and caused the Captain much trouble, disobeying his orders and prompting him to be unnecessarily harsh, besides quarreling among themselves. On Christmas Day the 'Tonquin' doubled Cape Horn. Early in February she anchored off the island of Owyhee, one of the Hawaiian group, then called the Sandwich islands. There the members of the expedition rested for 16 days. On March 22 they arrived at the mouth of the Columbia, where they had trouble in landing, eight men being lost in the first attempt. The 'Tonquin' anchored in Baker's bay, as the Lewis and Clark expedition had done. A site for the trading-house was selected near Point George and was named 'Astoria'. On June 5, 1811, the 'Tonquin' was sent up the coast with 23 persons on board, under Captain Thorn. Off Vancouver island he got into a quarrel with the Indians, who then, under cover of trading, swarmed on board, killing most of the white men, the survivors blowing up the ship and taking more than a hundred Indians with them to death. The news of this loss struck dismay in the hearts of the pioneers at Astoria, but they kept a brave heart and proceeded energetically to build their trading-house, a commodious mansion completed on September 16, 1811. They were awaiting the arrival of the party under Hunt.

In July 1810 Hunt started from Montreal, where he had equipped his expedition, and on July 22 he reached Mackinaw, the old French trading-post on the island of that name at the junction of lakes Huron and Michigan. There he recruited voyageurs. On August 12 the expedition started for St. Louis, arriving on September 3. St. Louis had grown now to a considerable frontier settlement and served as the last outfitting depot for the Indian trade of the West. On October 23 Hunt set forth in three boats up the Mississippi and thence 450 miles up the Missouri to the mouth of the Nodowa (or Nodaway), which he reached on November 16. Opposition from the Missouri Fur Company delayed him repeatedly. He did not resume his advance until April 28. Then he crossed the Black Hills of South Dakota and the Bighorn range of the Rocky Mountains. On September 24 he reached one of the streams tributary to the Columbia and came within sight of the Three Titans. The party crossed the desert that stretches between the Snake and the Columbia rivers. By this time they were short of food and suffering from hardships. It was December, and the snow impeded them in crossing the mountains. They lived on the flesh of horses captured from the Shoshone Indians. A milder climate and plenty of food gladdened them when they reached the Umatilla. On January 31, 1813, Hunt reached the falls of the Columbia and on February 15 he arrived at Astoria, after 11 months of wandering across the wilderness. The distance he and his party had

⁸'American History and Its Geographic Conditions', by Ellen Churchill Semple. Page 28.

traveled, from St. Louis to Astoria, was 3500 miles, although in a direct line it is only 1800 miles.

The news of the outbreak of war between Great Britain and the United States had reached Astoria, by sea, on January 15, 1813. On October 16 there appeared a vessel with agents of the Northwest company on board. These contracted for the purchase of the American company's property—"establishments, furs, and stock in hand"—for \$58,000. Astor's local representatives were largely Canadians with a friendly feeling toward the Northwest company. While the transfer was being concluded a British sloop of war arrived with orders to capture Astoria. The sale having been made, its terms were respected. "The American flag was replaced by the Brit-

Thompson, of the Northwest company, had tried to forestall Hunt's party, representing Astor's company, but he had been delayed in crossing the mountains. Nevertheless he laid claim to various points as he descended the Columbia and erected flagstuffs flying the British colors. On this performance the British government based its claim to suzerainty in 1826. This corner of the continent continued to be a disputed territory, but the establishment of the northern border of the United States was under way. Russian control on the Pacific coast had been fixed at 54° 40' north and Spanish, or Mexican, rule at 42°, leaving an interval of nearly 13 degrees, equal to 900 miles. There remained the conflict with Great Britain. In 1826 the 49th parallel of latitude was accepted tem-

PORTAGES BETWEEN THE GREAT LAKES AND THE MISSISSIPPI

ish, and Astoria was re-christened Fort George.¹⁹ The touch of military conquest given to the affair, by the presence of the British warship, caused the restoration of Astoria to the United States under the Treaty of Ghent in 1818, but it was held by the Northwest Fur Co. until 1821, when it passed with other possessions of that company into the hands of the Hudson's Bay Company.

For ten years after the capture of Astoria, scarcely an American was to be seen in this region. An agreement for joint occupation was made in 1818 between the United States and Great Britain, but this failed to decide the opposing claims and only served to accentuate the conflict of interests. The agreement that this region should be open to the inhabitants of both nations was for ten years, and in 1828 it was extended for ten years more. The Hudson's Bay Co. extended its posts; the Columbia River basin was occupied by British subjects and governed under British law. In the spring of 1811 David

porarily by both parties as the frontier up to the Rocky Mountains. Interest in the subject grew to excitement as migration over the Oregon trail increased. In 1843 an expedition of 1000 persons, including women and children, with herds of cattle and horses, trekked from Missouri to the valleys of the Willamette and Columbia. In 1844 another 2000 emigrants of like character joined them, and in the following year 3000 more. The Hudson's Bay agents objected to this peaceful invasion because it spoiled their hunting-grounds. Congress was slow to act, but, thanks to the exertions of Senator Thomas H. Benton, a treaty was concluded amicably in 1846, the British protocol being accepted, whereby "the Oregon territory was divided by the 49th parallel from the Rockies to the Straits of Fuca, and thence by a line following the main channel of these straits to the sea".¹⁰ Two years later, in 1848, Oregon was created a Territory.

A Contribution to the Study of Flotation—I

By H. LIVINGSTONE SULLMAN

*As one of those who, in 1905, were concerned in the discovery of the essential facts on which modern flotation is based, the author submits the following paper on the principles underlying what is now recognized practice.

Some of the earlier attempts to explain flotation will not bear close scrutiny; this is hardly to be wondered at in a subject whose facts even now lie so close to the border-line of our knowledge. On the other hand, many of the phenomena involved have received mathematical treatment too abstruse for the needs of the working metallurgist, who in turn has accumulated facts and an empirical knowledge of conditions often unknown to the mathematician. In this paper an endeavor is made to link-up and explain the complex of facts, in simple non-mathematical language, upon the broad lines of the molecular hypothesis, to the exclusion of operative detail.

In some quarters adverse criticism has been levelled against the original patentees of the froth-flotation process on account of the delay in publishing their experience and knowledge for the benefit of the industry; but this inaction was forced upon them and the owning company (Minerals Separation, Ltd.) by the litigation in which they have been involved almost continuously during the past 14 years.

The term 'flotation' is now narrowed in practice to ore-concentration processes wherein metallic sulphide or other particles suspended in an aqueous ore-pulp are recovered therefrom in an air-bubble froth. A short time since this method was more closely defined as 'froth-flotation' or the 'agitation-froth process' in order to distinguish it from other forms of float-concentration which employed other buoyant means; also from 'film' processes and from methods of oil-adhesion not involving buoyancy.

Such other processes may conveniently be grouped under the following heads:

(1) Those utilizing surface-tension effect at a water surface, or filming processes; such as De Bavay, Bradford, and MacQuisten.

(2) Methods where oil is employed both as the adhesive and the buoyant medium for the particles separated, or 'oil-buoyancy' processes. These include the use of a mass of oil, as in the Elmore bulk-oil process; in such the buoyant effect of the oil may be increased by the inclusion of some air bubbles, oil coated sawdust, or the like.

(3) Methods depending on the adhesion between oil or grease and the separable particles but not on final recovery by flotation, termed 'adhesion' processes, such as

the grease-plate, oiled-band, Murex, Cattermole, and similar methods.

(4) Processes where a mineral froth is produced through the agency of gases other than air, generated by chemical reactions, in which the minerals may sometimes take part; such as Potter, Delprat, and Froment.

(5) The Elmore vacuum process, and 'plus-pressure' methods, where air-bubbles are generated upon mineral and oiled particles by the aid of pressure differences.

The above classification is but a rough one, as connecting links exist between processes included in more than one of these classes; closer definition, however, would involve needless elaboration. Thus oil has been used in filming methods; oil-flotation has been employed to save metal suspensions not associated with gangue; and although in theory oil is not essential for froth-flotation, in minute amount it is still employed as a useful, if not integral, addition. No appraisalment of the respective merits of any of these processes is attempted or intended.

Nearly all sulphide ores, as well as those in which native metals and non-metals (sulphur and graphite) occur in practicable amounts, are amenable to concentration by flotation. Owing to the simplicity and economy of the operation and its ability to recover slined mineral, flotation has rendered profitable the exploitation of many hitherto valueless ores; thus a deposit of a sulphide ore containing only 0.8% copper with but small silver values is now being treated profitably. The same factors greatly increase the returns of many productive mines; it is computed that the method now deals with about 60,000,000 tons of ore annually.

Originally thought to be applicable only to the types of ore above-mentioned, experience has shown froth-flotation to have a much wider field. Oxidized ores of lead and copper (without the intervention of any 'sulphide-filming' process) are being treated commercially, while recent research has shown that other oxide minerals such as cassiterite may be flocculated and thereafter floated; even gangue-minerals betray distinct differences in their tendency to float or to remain wetted and sunken. Flocculation of a substance in the state of a true suspension is the step antecedent to its flotation, hence the problem in all cases is first to secure 'selective' or 'differential' flocculation of the mineral it is desired to float. With closer knowledge of the small yet often determinative margins of adhesion to water or other liquids which all varieties of minerals display, the possibilities of flotation promise enlargement in many directions, since any mineral flocculated can be froth-flotted; the effective separation of this from other substances is conditional upon the retention of the latter as 'suspensoids' in water. As

*Abstract of a paper presented to the Institution of Mining & Metallurgy, in London, on November 20, 1919.

to cassiterite, continued investigations indicate its successful differentiation from the various accompanying gangue-minerals, and the advent of a commercial flotation process at no very distant date; it has even been found possible to separate barite from its associated gangue by differential flotation. Froth-flotation proves to have applications beyond those of metallurgy, and is already applied in certain branches of industrial chemistry.

When an aqueous ore-pulp is agitated with a minute quantity of oil or other 'reagent', its content of sulphide mineral is yielded as a coherent froth on ceasing the agitation. Having regard to the large volume of prior work in oil-flotation and filming methods it may seem strange that so apparently simple a method was not discovered before. The main reason would appear to have been the assumption that oil was the necessary flotation agent and not air; hence previous inventors used oil in excess of the extremely small amounts which were later found to limit and determine froth-flotation, any excess over such quantities being inimical thereto. Cattermole in his ingenious process for 'granulating' the sulphide minerals into small sunken shot-like agglomerates, separable from the unaffected gangue particles by gravity methods, was the first to reduce the oil to an amount small relatively to the mineral saved. Upon further reduction of the oil to an almost disappearing quantity, and in the presence of an assemblage of finely divided air-bubbles, the Cattermole phenomenon was found to be reversed; in place of forming shot-like agglomerates the mineral now rose in completeness to the surface, as a mineralized air-froth.

The method did not therefore arise from employing oil as the buoyant medium for mineral, since oil ceased to act as such when its volume becomes very small; a mineral-sinking stage is passed through before the proportion becomes sufficiently minute to permit the production of a froth. In 1903 a patent was filed[†] for separating mineral from an ore-pulp by sending through it a current of air-bubbles laden with the vapor or spray of oil. This method, however, did not lead to the production of a froth, nor to any practical results, as the other antecedent conditions essential for froth-formation had not at that time been ascertained; it is now known that to introduce a relatively substantial film of oil upon the interior of a bubble is to prejudice flotation of the mineral. It was also found that ore particles could be temporarily suspended in the froths yielded by aqueous solutions of amyl alcohol and other substances, not so readily in any of soap and not at all in those of saponin, ox-gall, or tannic acid; but for similar reasons these experiments were at that period unproductive of practical result.

It was not until later that the necessary minuteness of the oil amount was realized; indeed froth-flotation does not depend *essentially* upon the use of any oil whatever, as air-bubbles will readily adhere to metallic sulphide and other particles in its absence; oil, though a useful auxiliary, is neither causative nor a necessary inter-

mediary. Apart from the use of non-oily and completely soluble reagents such as cresol and amyl alcohol, a simple current of air-bubbles alone, passed through an aqueous ore-pulp, will yield practical flotation results. L. A. Wood devised a sub-aeration machine of this type which did excellent work, even of a 'differential' character. This is not surprising, since mineral particles of considerable size float freely by surface-tension, and many finely divided particles are absorbed at a plane water-surface which may be regarded but as a portion of a bubble of infinite diameter.

Prior to or shortly after Cattermole's invention, which in 1905 had been introduced on a commercial scale in Australia, a large amount of work had been done in 'oiling' or 'filming' processes. Several methods had achieved success, notably those of the Elmore (vacuum) process, plants for which were installed in various countries; of Potter, Delprat, and De Bayay, at Broken Hill, and others.

Froth-flotation was, therefore, the final link in a long chain of effort. All these methods were developed empirically, physical and chemical science having afforded little if any previsionary aid; success in every instance was attained by methods of patient trial. Science even yet is unable to offer a full explanation of all the facts involved, although the actual procedure is so simple, and the results so immediate, that at first sight an equally concise theory would seem possible.

The essentials of froth-flotation are that an aqueous ore-pulp, in general not less than four parts by weight of water to one of ore, shall be agitated for a longer or shorter period with certain reagents, which may conveniently be classified as follows:

(a) A froth-producing material, such as, cresol, amyl alcohol, the soluble portion of an oil; this by slightly reducing the surface-tension of the water permits the formation of an extensive bubble system, or froth, on the surfaces of which the mineral particles become attached or adsorbed.

(b) A froth-stabilizing substance, usually a minute amount of insoluble oil; this is adsorbed at the sulphide mineral surfaces and by increasing the water-mineral contact-angle stabilizes the composite froth to an extent greater than is possible with untreated particles. The oil-film on the floated mineral must be of ultra-microscopic tenacity.

(c) A gangue modifying addition (a mineral acid, alkali, certain alkaline or other salts, some sds), which acts by increasing the adhesion between the gangue particles and water; that is, intensifying the water-wetting effect and preventing their flotation by air.

Requirements (a) and (b) may be furnished by a single oil of a suitable character.

Thorough agitation of the ore-pulp with the reagents is necessary:

(1) To secure uniform suspension of all ore-particles in the water in order to ensure the maximum wetting effect possible at this stage, and to disseminate the frothing agent through the water;

[†]Sulman and Picard, No. 20,419, of 1903.

(2) To break-up and distribute the immiscible oil in order to permit the uniform coating of the sulphide particles with a film of ultra-microscopic thinness, a step akin to the prior temporary emulsification of the oil;

(3) To allow the modifying agent to deflocculate agglomerates of the particles it is not wished to float, and to free the more floatable particles from such agglomerates;

(4) To promote some degree of flocculation of the particles it is desired to float.

5) The agitation system employed in the older 'standard' Minerals Separation system also serves to introduce the air into the ore-pulp, and there to break it up into minute bubbles, resembling an air-water emulsion. But if the first four of the above conditions are provided by the preliminary agitation, a certain time-factor being necessary, the air-bubbles may be produced otherwise and, as in sub-aeration apparatus, showered upward through the prepared pulp.

The explanation of flotation may be based on the differences shown by various substances in the degree to which they are 'wetted' by water or other liquids. Complete immersion of a solid in a liquid, even if the former be devoid of an actual or hypothetical air-film envelope and therefore involving actual contact, does not imply the complete wetting of one by the other, nor even that two different solids immersed in the same liquid will be wetted to a similar extent. On withdrawing the solid, it may, according to the nature of its surface (a property as inherent as its density, hardness, or color), tend to remain 'wet' in greater or less degree, or may apparently repel the moisture from its surface with less or greater rapidity and so become wholly or partly 'dry'. Wetting, which depends on the degree of adhesion established at the plane of contact between liquid and solid, is therefore a condition of wide variability, and a theory of flotation must be based largely upon the physics of wetting.

Substances capable of being wetted completely by any liquid, given sufficiently fine sub-divisions and neglecting effects due to differences in density, become true suspensions therein, that is, 'suspensoids' or possible 'sols'. The first tendency of such suspensions to become less completely wetted due to decreased adhesion between liquid and solid, is shown in the coagulation of sols and flocculation of suspensoids. When this step has been made, it is usually easy to take advantage of the decreased wetting and to enhance the 'drying' process by bringing a sufficient area of the solid into contact with air.

The particles may then appear to be thrust partly from the water into the air, either at a plane-water or a bubble surface, where they are held by the surface-tension of the liquid. The phenomena of flocculation, adsorption, and air-flotation are thus closely related stages in differential wetting, and the latter is at the root of all flotation phenomena.

The molecular principles involved will be reviewed briefly, but it may here be stated that the degree of wet-

ting may be influenced by the molecular porosity of the solid surface, and indicated more or less quantitatively by the 'contact-angle' made between the free surface of the liquid and the solid.

Such views supersede the previous ideas which endowed solids with specific 'surface-energies' supposedly capable of bringing about air or gas-condensations upon them in preference to liquid adhesions. Inasmuch as flotation effects were first observed to be pronounced in regard to many of the elementary solids, such as finely divided metals, the non-metals boron, carbon, silicon, sulphur, and selenium, and scarcely less so for metallic sulphides, most of these being substances of high chemical energy in relation, for example, to oxygen, the view was held that the chemical energy of the solid was reflected in a like surface-energy. We now know that where no actual chemical reaction is involved, the surface molecular-energy of any solid has little or no direct connection with the inter-atomic forces which constitute chemical activity. Moreover, the earlier theories did not account for all the facts, since an element of such low chemical activity as gold floats as readily as the more chemically energetic elements carbon and sulphur, and the various sulphides; further, completely oxidized compounds such as calcite, copper-carbonate, cassiterite, and several gangue-minerals can be floated almost as readily as the elements and sulphides. The surface-energy of solids, though as essential a factor in wetting phenomena as that of liquids, has nothing in common with the chemical activity of the solid.

Even in regard to the film-flotation of dense solids, erroneous ideas were prevalent; the particles were often thought to be borne in a depression of the resistant water surface as in a hammock, instead, in fact, of being suspended in the liquid, by the tension of the liquid surface.

The physical reactions concerned deal with molecular forces of high intensity, which act only over minute distances; it is necessary to examine these in some little detail.

Although the mathematical theory of surface-tension enunciated by Laplace remains of fundamental value, it is alone insufficient to account for an accumulation of newer facts. Laplace, who lived in the phlogiston era of chemistry, regarded solids and liquids as practically continuous media, their particles as stationary, existing in close contact without spatial divisions and devoid of the polarity which modern views on crystallography demand. He therefore treated of liquid and solid surfaces as mathematical planes; but the problems presented by colloid chemistry and physics, and the vast technical industries these affect (flotation may be regarded as one) are no longer explicable on this basis.

(To be continued)

AN ADVANCE STATEMENT by the U. S. Geological Survey gives the value of the mineral products of Alaska for 1919 as \$18,850,000. Gold produced is valued at \$9,000,000, and since 1880, when the mining industry began in Alaska, gold produced totals \$437,400,000.

Fine-Grinding in Ball-Mills

By HENRY HANSON

INTRODUCTION. The adoption of ball-mills as grinding-machines to reduce the ore of the Inspiration mine started a ball-mill wave that swept over every mining district of the country and from the time the Inspiration mill was put into successful operation there has been practically no new plants of importance in which some type of ball-mill or cylindrical mill, as a grinding-machine, has not found a place.

The great enthusiasm brought about by the simplicity

CRUSHING RESISTANCE OF DIFFERENT ORES. Some interesting work has been done by Luther Lenox of the Portland Mining Co. on the crushing resistance of various ores. Some time ago, when at Cripple Creek, it was my privilege to talk to Mr. Lenox about these experiments and to see the various screened products from these laboratory tests in glass bottles, whereby a graphic view was obtained of the crushing resistances offered by the different ores at the different stages of diminution. By

*The crushed ore between the designated limits of size, as shown on the graphs.

of ball-mill operation as signalized by the Marcy slogan "one easy step", for various reasons, has been somewhat dampened by the experience of the past four years in operating plants; first, it has been found that the big capacities promised on the soft Inspiration ore do not apply to the harder ores of other districts; secondly, in some instances where the ball-mill was installed to take a crusher-product, it has been found a decided advantage to break away from the "one easy step" and place cracking-rolls between the crusher and the bin supplying the ball-mill feed. Thus, by delivering to the ball-mills a much finer feed than the crusher-product, the capacity of the ball-mills has been greatly increased and the cost of crushing noticeably reduced; thirdly, the maintenance of the ball-mill has been much heavier than the earlier experience indicated. This, no doubt, is largely due to inferior manganese-steel being used in manufacture, owing to war conditions, and to the increased cost of these inferior products.

The ball-mill, however, is no longer an experimental machine. Its usefulness has been firmly established. In fact, the ball-mill may justly be termed a standard machine in all fine-crushing plants, but it has its limitation, and even now it would be ill-advised to install ball-mills on a large scale upon the basis of single or two-stage reduction without thorough preliminary experimental work to determine such problems as the capacity of the mill on the particular ore to be handled, as well as to ascertain the most suitable feed to deliver to the mill for the greatest economy in operation. It has been amply demonstrated during recent years that a ball-mill has not nearly as great a capacity when taking a crusher-product having a maximum size of $2\frac{1}{2}$ inches as when taking a feed having a maximum size of one inch or one-quarter inch.

†See Bulletin, A. I. M. E. August, 1918.

the courtesy of L. D. Ricketts, I was given the data showing the comparative crushing resistance of Inspiration, New Cornelia, and Portland ores, but before quoting this information, I want to state briefly how the data were obtained.

The grinding-machine used in the Lenox experiments was a cylindrical tube-mill, 8 inches in diameter by $12\frac{1}{2}$ in. long. This mill was charged with about $7\frac{1}{2}$ lb. of $\frac{3}{4}$ -in. steel balls, one pound of ore, and an equal weight of water. The mill was revolved at a speed of 84 r.p.m. The feed to the mill in each case was identical as to screen-analysis, being artificially prepared from screened products. The period of grinding was five minutes on the first prepared charge of ore and ten minutes on the second prepared charge from each of the ores upon which the comparative tests were made.

After each of these grinding operations, the mill-charge was dried and a screen-analysis was made. The screen-analysis of the feed to the mills and the discharge from the mill after the five and ten-minute grinding-periods respectively, are shown on the accompanying tabulations, which also show the relative grinding-resistance of the Inspiration and New Cornelia ores. Sheet No. 1 shows the plotted curves on the plus 200-mesh. On Sheet No. 2, in addition to the curves of sheet No. 1, are plotted

the minus 200-mesh on a smaller scale to bring out the minus 200-mesh characteristics of the ore.

From the tabulated data using 1.00 as the grinding-resistance of the Portland ore, that of New Cornelia is 0.75 and that of Inspiration is 0.45, as shown on the tabulated data and plotted curves of Mr. Lenox's tests.

In Bulletin No. 140 of the American Institute of Mining Engineers, Mr. Lenox, in a splendid article on the 'Crushing-Resistance of Various Ores', shows the comparative crushing-resistance of 23 different ores tested in a way similar to that described above. Taking the Portland ore in these tests as having a crushing-resistance of 1.00, that of the Calumet & Hecla jig-tailing was 1.33, and that of the Ray Consolidated was 0.37. Of the 23 samples tested, the last two represent the two extremes. The Calumet & Hecla jig-tailing, the highest in crushing-resistance, is shown to be 3.6 times that of the Ray Consolidated, the lowest in crushing-resistance.

Just how reliable the data obtained in such a series of tests would be in making estimates as to capacities of ball-mills on different ores based on comparative crushing-resistance tests, I would not venture to state, but I believe that preliminary tests of this kind when using representative samples of ore from a mine, the crushing-resistance of which has already been determined by actual mill-operation and comparing this to an ore whose crushing-resistance has not been determined in actual mill-practice, should give a good indication of the capacity of ball-mills upon the latter ore.

There is, of course, the objection to this kind of an experiment that it is 'batch' grinding and does not conform to the regular ball-mill practice of continuous discharge; and there is the further objection that on ores of different crushing-resistance the blow required to crush the ore would have to be increased in proportion to the increase in crushing-resistance and therefore the grinding media used in one case would not be suitable in the other. In an article in Bulletin No. 146 of the Institute, by E. W. Davis, to which I shall have occasion to refer later, it is indicated that the size of the balls used in ball-mills should be such as to make it possible for the smallest ball to break the hardest and largest piece of ore fed into the mill. The experiments carried on by Mr. Davis do not indicate that a $\frac{3}{4}$ -in. ball is large enough to break a hard ore having a maximum size of $\frac{1}{4}$ in. as satisfactorily as larger balls. In other words, while the $\frac{3}{4}$ -in. balls might do the most satisfactory work on softer ores, the same thing would not necessarily apply on ores having the greater crushing-resistance. It is, of course, also impossible to determine the relative amount of work done on the different ores beyond minus 200-mesh by the ordinary screen-analysis. This further complicates the problem of finding the exact relative crushing-resistance of different ores. Nevertheless, if it is found that for the most economical metallurgical results, it is necessary to reduce an ore to a point where a definite proportion is to be minus 100 or 200-mesh, and any additional reduction in size beyond that point does not affect the metallurgical recovery, then it would seem that for all practical pur-

poses the only thing that needs to be determined is the machine or machines that will have the capacity to reduce the required tonnage of ore to the necessary fineness in the most economical way. It would therefore appear that while tests like those made by Mr. Lenox may not give an absolutely reliable basis for making estimates as to the exact capacity of a ball-mill of a given size supplied with a feed of a given size, yet I am of the opinion that a reasonably close estimate may be made from such tests based on the comparative grinding-resistance of the different ores. The tests show that there is a wide difference in the work required to reduce an ore like that of the Portland mine as compared to the work required to reduce a much softer ore like that of the Ray Consolidated. That there is great variation in the capacity of a ball-mill on two different types of ore, not only in the capacity of the mill but also in the wear of balls and liners, is proved easily in actual practice by making a survey of the data obtainable in operating plants where these machines are in use. It is, therefore, not surprising to find that a ball-mill rated at 200 or 250-ton capacity based on the duty of mills when working on soft ore has this nominal capacity cut in two when the mill is put to work on a harder and different type of ore.

At this point I would like again to refer to the article by Mr. Davis on 'Fine-Grinding in Ball-Mills' in greater detail. In this paper the many phases of fine-grinding in ball-mills are discussed exhaustively, not only from the standpoint of the particular test-runs in the series of experiments but also from the strictly theoretical viewpoint of ball-mill grinding. Without making any comments on the purely theoretical part of the article, I would like to summarize briefly the scope of the Davis experiments and the conclusions reached.

The ore used in the tests was a hard and tough iron ore from the Mesabi range; the hardness was 7 and the specific gravity of the ore was 3.4. This high specific gravity was due to a high magnetite content. The purpose of the tests was to find the most economical way of reducing the ore from $\frac{1}{2}$ -inch to 200-mesh. The equipment used was an 8-ft. by 22-in. Hardinge conical mill and a duplex Dorr classifier of the bowl type. The mill carried a load of 28,000 lb. of balls. Tests were made on light and heavy feeds, open and close circuit, single and two-stage crushing, large and small balls, and various speeds of the mill.

The deductions made from the tests can be summarized as follows: An increase in the tonnage fed to the mill resulted in an increased crushing efficiency; close-circuit crushing is more desirable than open-circuit; two-stage crushing is more efficient than single-stage. The proper adjustment between the size of the balls and the speed of the mill can be secured by a screen-analysis of the discharge from the mill or from the sand from the classifier. If this sand is crowded with the finer sizes, then either the balls are too large or the speed of the mill is too high. On the other hand, if the classifier sand is crowded with the coarser sizes, the indications are that the balls are too small or the speed of the mill is too slow. The smallest

ball of uniform size that can crush the ore should be used, but balls smaller than can crush the largest particle of ore should not be kept in the mill, as they take up space, absorb power, and are inefficient for crushing. These deductions are interesting, even though it is impossible to subscribe to all without reservations. It is obviously an advantage to have the ball-load consist of balls no larger than are required to do the work, because more of the smaller size of balls can be charged to the mill, and if the feed to the mill is a sized product having $\frac{1}{2}$ -inch as the maximum size, as was the case in the Davis tests, it is apparent that balls approaching more nearly to uniform size can be used than if a mixed feed or crusher-product was delivered to the ball-mill.

The experience of ball-mill practice has been that when a coarse mixed feed is delivered to the mill, it is necessary to maintain a ball-load of mixed sizes; and in tube-mill practice it has always been my experience that pebbles of mixed sizes gave better grinding-efficiency than pebbles of uniform size.

Anyone that has attempted to start a tube-mill with pebbles of the same size, especially if the feed to the mill is such as to require pebbles of large size to crush the ore, has found that a mill operating under these conditions gave unsatisfactory results and that the efficiency of the mill gradually increased as the pebbles wore down to a variety of sizes. Furthermore, to the best of my knowledge there is nothing in ball-mill experience that would indicate that the size of the smallest ball in the ball-charge to the mill should be such as to make it possible for it to break the hardest particle of ore in the mill-feed, and such objections to the use of small balls as that of preventing the freer migration of the ore through the mill does not carry much weight, for when a mill is in action there is ample chance for the movement of ore through the mill under proper pulp-dilution, without going into such refinements as the interstitial spaces between the balls. It must also be borne in mind that the pressure exerted on a particle of ore, or the blow struck by a ball, is not only dependent upon the mass of the ball and the distance of the drop, but also upon the position of the particular ball in relation to the other balls in the mill.

While it is impossible to be in full accord with the deductions drawn by Mr. Davis, his many test-runs render his article exceedingly suggestive. It would be interesting to know what machines will be adopted to reduce the ore in question from a crusher-product to the final 200-mesh fineness. I opine that three-stage crushing at least will be employed, no matter what machines are used in the operation.

Knowing the character of the ore, the fineness to which it must be reduced to obtain economic metallurgical results, and the tonnage to be handled, the fine crushing problem should resolve itself into one of the following methods, if ball-mills are to have a place in the fine-crushing operation.

1. Reduce crusher-product in a single-stage ball-mill operation.

2. Reduce crusher-product in a two-stage ball-mill operation.

3. Reduce crusher-product in cracking-rolls followed by single-stage ball-mill operation.

4. Reduce crusher-product in cracking-rolls followed by two-stage ball-mill operation.

5. Reduce crusher-product in coarse and fine rolls followed by single-stage ball-mill operation.

6. Reduce crusher-product in coarse and fine rolls followed by two-stage ball-mill operation.

I am, of course, not prepared to prove that one of these combinations is the best and only way to reduce ore, for I am fully aware that in many instances the Symmons disc-crusher in one or more stage-crushing can practically do the same work as the rolls, nor am I unaware that the stamp in some instances seems to defy replacement. And furthermore at the present time there is much work being done to place an improved mechanical rod-mill on the market. The grinding principle of rod-mills—a series of small rolls—is good, and it is possible that a machine of this type, when mechanically right, will make inroads upon the work of the ball-mill. It may be suggested further that if the ore is reduced to 4 or 8-mesh in rolls, why not complete the grinding operation in tube or pebble-mills in accordance with the old practice. These are all questions that are rightly open to discussion.

It is, nevertheless, a fact that nearly all late installations of fine-crushing equipment for reducing ore for all-slime, and especially for concentrating purposes, embrace one of the six combinations mentioned above. While this is not proof absolute, it is at least good evidence that one of these combinations in fine crushing conforms to the best practice of the day.

In commenting on the first of the six combinations, it would appear that to reduce an ore from a crusher-product having a maximum size of 2-in. or $2\frac{1}{2}$ -in. ring to a 50-mesh product in a single-stage ball-mill operation is only justified in plants of limited capacity or in case of an ore having a low crushing-resistance, and even in this latter case it would seem of doubtful economy and become a question of local determination. The two-stage fine-crushing combination, on the whole, would seem advisable where the capacity of the plant requires two grinding-machines, and the present practice would indicate that a two-stage reduction from a crusher-product to an all-slime product is not only more elastic but also more economical than single-stage reduction.

In some recent fine-crushing equipments it has been found necessary, or at least advisable, to precede the two-stage ball-mill operation with cracking-rolls in order to give the primary ball-mill a finer feed than the crusher-product. It is, of course, possible that using larger balls in the primary mill might overcome the difficulty of crushing exceptionally hard tough ore. At the Alaska Juneau, I am told, 5-in. balls that failed to do satisfactory work were replaced with 7-in. balls to great advantage, increasing the crushing-efficiency of the mill.

In the combination having coarse and fine roll-reduc-

tion preceding the final grinding in ball-mills, the practice at the Alaska Gold mill is a good example. The ore is there reduced to about 8-mesh in coarse and fine rolls, and it is doubtful if this type of ore is now being reduced anywhere from a crusher-product to 8-mesh in other machines equally economical. It would certainly appear that it cannot be done in ball-mills. It is, of course, difficult to make true comparisons of cost between different plants, as identical conditions as to character of ore and final diminution of ore rarely obtain. There are also certain objections to dry-crushing in rolls, especially where the ore is soft and dry on account of 'dusting'. In this connection, it is worth recalling that such plants as the Anaconda and Utah Copper, where dry-crushing in rolls plays such an important part, little or no inconvenience is experienced in this regard.

Two-stage roll operation followed by two-stage ball-mill operation may be justified in exceptionally large-scale operations where the crushing resistance of the ore is high and great fineness is required in the final product. Rolls, while they require more attention than ball-mills, are more or less fool-proof machines and they are exceptionally elastic as to capacity. The wear on roll-shells, when compared with the wear on balls and liners in ball-mills, is so much less as to offer no comparison; this, in part, may be explained by the fact that there is less wear in crushing ore dry than in crushing it wet. Moreover, when a roll receives a heavy feed a great deal of the crushing is 'ore against ore', as only a small part of the ore actually comes in contact with the roll-shell. In ball-mills, the crushing is either by impact or attrition; in either case there is certain to be considerable wear of 'iron against iron'.

There may be those who are so firmly wedded to the ball-mill that they object to complicate the crushing scheme by the introduction of rolls, and it is possible that a primary ball-mill of exceptionally heavy construction, designed especially for coarse crushing with large balls, would do in a single operation practically the same work as would be done by coarse and fine rolls. This method, even if it required a three-stage ball-mill operation, would simplify the final crushing, but I believe at a considerable increase in operating costs as compared with dry-crushing in rolls.

A single operation, such as the "one easy step", would greatly simplify the grinding problem, but a machine like the human animal has its limitations and it is apparent that, as yet, there is no way to escape from stage-crushing. In large operations, we may look for refinements in more stage-crushing. Certainly any progress in rod-mill reduction would depend on sized feeds, and a series of stage-reductions.

Such phases of ball-mill crushing as the relation of the wear of the balls to the speed of the mill, the size of the ball and the volume of the ball-load, offer interesting problems for definite and conclusive solution. Mr. Davis, in his paper, makes the statement that the ball-load should not occupy more than 60% of the mill-volume on account of interference between the balls, and not less

than 10% of the mill-volume on account of slippage. This range seems much too great, for it is evident that carrying a load of only 10% of the mill-volume does not work the mill to its capacity. There are also other reasons why the volume of the mill occupied by the ball-load should bear some definite relation to the total volume of the mill. Some time ago my attention was called to the work of a tube-mill in which pebbles were replaced by balls. The ball-load was made up of the same weight as the original pebble-load; the wear of the balls under these conditions was almost prohibitive. When the inside diameter of the tube-mill was reduced from 5 ft. to 3 ft. by wooden lagging, there was not only a saving in power but the consumption of balls was also greatly reduced without reducing the grinding efficiency of the mill.

Similar reductions in the diameter of the Hardinge mills at Anaconda when using steel balls instead of pebbles was made for a good and sufficient reason. Likewise a reduction in the speed of mills has sometimes resulted in the economy of power and wear, without decreasing the efficiency of the mill.

The crushing in ball-mills is by impact and attrition. The amount of work done by impact is naturally dependent upon the cascading action of the balls. This latter action is in turn dependent upon the speed of the mill. When treating fine mill-feeds, the crushing can be done by attrition, and there should be less occasion for impact crushing and it would be interesting for some one in a position to do so to determine the relative ball-wear and crushing-efficiency when operating mills at such speeds as will give rolling and cascading action to the balls.

THE U. S. Bureau of Mines gives some interesting details of the mine operations at the Ottawa shaft of the Oglebay-Norton Co., Montreal, Wisconsin. Typical sub-level open stoping is used, as the capping rock is hard and stands well, with small orebodies at the top of not over 50 ft. average width. Raises for chutes are driven frequently enough so that no shoveling is required. This is one of the few companies on the Gogebic range using underground magazines for explosives. The usual precautions are taken by having separate magazines for caps and dynamite. All caps are crimped on standard fuse lengths by a powder man on each shift and requisitions, issued by the shift boss, are required for dynamite and caps. A compressed-air receiver is situated on each working level in the mine, instead of having a large receiver near the compressor. This practice is followed, according to the superintendent, to furnish dry air to the machines, and at a higher pressure than could be obtained by the usual practice of having the receiver on the surface. A machine-drill man inspects all machines each day. Drills needing repairs are taken to a repair shop on the main level and repaired at once. This mine has an underground drill-sharpening and blacksmith shop. Oil is used for fuel and the gases are exhausted into the upcast main hoisting shaft. The shop is situated at a station near the main hoisting shaft.

The Reaction of the Manganese Industry

By H. A. C. JENSEN

*During the first nine months of the year 1919, 31 shippers of high-grade manganese ore reported shipments of 53,772 tons of ore containing 35% or more of manganese. During the corresponding period in 1918, 192 similar shippers reported shipments of 228,901 tons of ore containing 35% or more of manganese, or 4.25 times as much. From July 1 to September 30, 1919, inclusive, only 9233 tons of high-grade ore was shipped, and virtually all of this came from Arkansas and Montana. California and Colorado, which had previously been two of the largest producers, shipped practically no ore of this grade. The decrease in the shipment of high-grade ore during the first half of the year was continued into the third quarter, in most districts reaching the point of no shipments whatever.

The shipments of ores containing 10 to 35% of manganese for the first nine months of 1919 amounted to 164,539 tons, whereas the shipments for the corresponding period of 1918 amounted to 595,708 tons, or 3.62 times as much. During the third quarter of 1919 the shipments of ore of this grade amounted to 78,381 tons, which was almost as much as was shipped during the first six months of the year. This substantial increase came almost entirely from Michigan, Minnesota, and Nevada. The increase in the output of Michigan and Minnesota was due largely to the opening of the lakes to navigation during the summer rather than to an increase in demand, although the high iron content of both the intermediate and the low-grade ores shipped from Michigan and Minnesota, particularly from the Cuyuna range, has probably contributed largely to the demand for ore from those districts.

The operators in Nevada have been able to maintain a high rate of production because practically all the ores mined there are sold to smelters for use in fluxing, so that the conditions which apply to ore used in the manufacture of manganese alloys do not affect the Nevada industry.

The shipments of 5 to 10% ore during the first nine months of 1919 amounted to 83,560 tons, all of which came from Minnesota. During the third quarter of the year Minnesota shipped 66,688 tons of this ore, which was more than 4.26 times the shipments from this State for the previous six months. This great increase in shipments was due largely to the opening of the lakes to navigation and to the subsequent shipment of ore previously mined. During the first nine months of 1918 the shipments of ore of this grade were 188,186 tons, or 2.25 times the shipments during the first nine months of 1919. The production of low-grade ores during the first

nine months of 1919 more nearly equaled the production of like ores during corresponding periods in 1918, but the same cannot be said of the production of the higher-grade ores. The following table shows the shipments by States for the first nine months of 1919:

Manganese and Manganiferous Ore Shipped During the First Nine Months of 1919, by States

	35% or over	10 to 35%	5 to 10%			
	Number of shippers shipped	Gross tons of tonnage shipped	Number of shippers shipped	Gross tons of tonnage shipped	Number of shippers shipped	Gross tons of tonnage shipped
Alabama	1	40				
Arizona	3	273	1	1 900		
Arkansas	5	2 200	1	78		
California	7	10 942				
Colorado	2	13 117	*1	*9 861		
Georgia	1	48	1	3 061	2	210
Michigan			1	23 221		
Minnesota			3	12 122	2	87 334
Montana	6	23 070				
Nevada	1	78	3	65 800	1	1 016
New Mexico			3	12 398		
North Carolina			1	30		
Tennessee	3	121				
Virginia	5	3 763	1	5 765		
Wisconsin					11	111 013
Total	34	53 772	*16	*161 539	15	183 560

*Fluxing ore from Colorado not reported quarterly and not included in totals.

*Ore from Wisconsin containing approximately 5% manganese not included in totals for the United States.

The imports of manganese have in general suffered a decrease as great as that of the domestic shipments. The imports for the three months ending September 30, 1919, have been only 43,426 tons, whereas those for the previous six months were 225,985 tons, making a total for the first nine months of the year of 269,411 tons. Had the rate reached during the first six months been maintained the imports for the first nine months of the year would have nearly equaled those of the corresponding period of 1918.

During the third quarter of the year only 30,136 tons of ore and oxide were imported from Brazil, which is about 17.4% as much as was imported from that country during the first six months. Costa Rica, England, Mexico, and Asiatic Russia contributed most of the remaining 13,290 tons imported during the third quarter. The imports from Asiatic Russia during the third quarter were 4089 tons. These were the first imports from that country during 1919. The following table shows the imports of manganese ore by countries for the first nine months of 1919:

Manganese Ore and Oxide Imported into the United States During the First Nine Months of 1919

Country	Long tons	Country	Long tons
Portugal	400	Colombia	10
Russia (in Europe)	1,327	Ecuador	20
England	4,432	British India	1,500
Canada	207	China	1
Costa Rica	9,988	Hongkong	1,260
Panama	2	Japan	508
Mexico	5,309	Russia (in Asia)	4,089
Cuba	33,788	Australia	548
Argentina	2,365	British South Africa	144
Brazil	203,132		
Chile	441	Total	269,411

*A preliminary report, U. S. Geological Survey.

The decrease in imports might be encouraging if it was the result of an increased use of domestic manganese ore in the steel industry, but no such increase has been reported. As it is the custom of the makers of ferro-manganese and steel and the brokers to maintain stocks sufficient to supply the demand for six or eight months, the decrease in the domestic production and imports indicates that a great supply is on hand which cannot be utilized until the steel industry becomes normal. The decrease in imports must therefore be considered temporary, and a reaction may be expected soon after the steel industry becomes stabilized. The principal reasons for a probable increase in the imports of manganese are the high grade of the foreign ores, the cheapness with which they can be mined, and the low cost of transportation.

Since the Armistice was signed the decrease in the production of domestic manganese ore has been continuous and rapid. Nearly all the domestic ore shipped in 1919 has been shipped under war contracts that did not expire until the summer of the year. With the expiration of these contracts very few producers have been able to market their ore, and the industry has therefore suffered a serious reaction, which has caused considerable losses to many operators.

The causes that have combined to produce the present conditions are many and various, and notable among them are the sudden removal of the war demand, the release of shipping for importation of foreign ore, labor troubles among both producers and consumers, the inability of the domestic ore to compete in cost and grade with foreign ore, the large stocks on hand, and the conservative interpretation maintained as to the scope of the War Minerals Relief Act.

The cessation of the war demand for steel was necessarily followed by a decrease in the demand for manganese, and consequently there was soon accumulated considerable stocks of manganese. These cannot be utilized until the steel industry becomes adjusted to peace conditions and the peace demand and production of steel increases and becomes stable.

Labor conditions, particularly in the coal and steel industries, have decreased the production of steel and have therefore diminished further the demand for manganese. This demand is based primarily on the actual production of steel; consequently before an increase in the demand for manganese is possible the actual production of steel must be materially increased; an increase only in the demand for steel can have no effect on the manganese industry until the steel producers are able to respond to that demand. There is now undoubtedly an increasing demand for steel, but an increased production of steel is at present probably impossible on account of the conditions of labor in the steel and coal industries.

The tremendous impetus given to the domestic manganese industry during the War was due not so much to economic conditions as to strategic considerations. Early in the American participation in the War it became evident that the country would soon be facing the danger of

a very serious shortage of manganese, due, of course, to the success of the German submarines in sinking cargo ships, to the increasing demand for transportation of men and supplies overseas, and to the tremendous increase in the demand for war materials made by the American government upon the steel producers. To avert this danger a carefully planned campaign for the encouragement of domestic production of manganese was begun. This campaign consisted of a careful examination, largely by the United States Geological Survey, of all the known possible domestic deposits, together with a direct and general appeal by several Government agencies to the producers for more manganese. The response with which this appeal was met is best indicated by the fact that in the third quarter of 1918 the United States supplied almost a third of its requirements.

Much of the production was made at an actual loss, in spite of the high prices current during the period. Some of the loss was due to the fact that the actual cost of mining the ore was greater than its price. At some properties, however, the ore was produced at a profit, but the demand was of such short duration that a sufficient amount of the ore could not be sold to cover the initial cost of purchasing and developing the properties.

The cost of mining manganese in the United States being so much higher than the cost in foreign countries and the grade of the domestic ore in general being lower than that of the foreign ore, the domestic producers cannot readily compete with the foreign producers under the present tariff as long as sufficient shipping is available.

An effort is being made to put a protective tariff on many minerals, metals, and alloys, manganese among them. If this effort is successful the manganese industry will undoubtedly enjoy considerable immediate prosperity, but in a very few years of normal steel production, four or five at the most, the known manganese resources of the country will be exhausted. Tariff hearings on manganese have been held in Congress, but no definite action has been taken so far. In the event of another war after the domestic manganese deposits had thus been practically exhausted, or at least very seriously depleted, the country would be facing a much greater danger than it did in the critical days of 1917 and 1918.

During October \$12,269,679 in silver was exported from the United States, over 90% of which was shipped to China, and \$8,722,430 in silver was imported, the bulk of which came from Mexico. The following tables show a comparison of imports and exports during October 1919:

Silver Exports to		Silver Imports from	
China	\$10,266,671	Mexico	\$6,060,765
Hongkong	1,013,582	Peru	990,216
Canada	309,979	Central American States	803,635
England	291,422	Canada	515,284
Mexico	133,758	Dutch East Indies	164,959

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

HOLIDAY SHUT-DOWN AT BISBEE.—SWISSHELM PROPERTY SHIPS.

JEROME.—The Shea Copper Co. will start shipping ore early in January, arrangements having been completed with the United Verde Extension smelter to handle from 300 to 400 tons of ore per month. The ore is high grade, with copper running from 10 to 25%, and should net from \$150 to \$200 per ton. Approximately half a million dollars worth of ore is said to be blocked out underground between the 200 and 300-ft. levels. Control of the prop-

smelter was begun several months ago, but as the railroad was under lease to the Arizona United mines, a fleet of three four-wheel-drive trucks was purchased and shipment started from Cochise. Lately bad roads caused by heavy rainfall have retarded shipment to a great extent. With the opening of rail communication the volume of shipment is expected to be increased. There is enough ore in sight to warrant shipment at the rate of one car per day for several months. The power-plant will be put in operation when a car of fuel oil is received. Ed C. Rice, superintendent, will start driving on the 400-ft. level of

MINE AND MILL OF THE MIAMI COPPER CO., MIAMI, ARIZONA

erty has passed from D. J. Shea and the new management intends to sink the shaft 200 ft. deeper and do considerable lateral development.

BENSON.—The Mining & Development Corporation, with headquarters at Benson, has been made a party to the lease of the Dragoon Northern railroad extending from Dragoon, 23 miles east of Benson on the main line of the Southern Pacific, northward to Johnson where the company's Copper Chief mine is situated. The first two carloads of ore from the mine under the new arrangement were sent to Douglas for smelting during the latter part of December. For several months the company has been developing the Copper Chief on which it holds a ten years lease, but as three large orebodies were encountered shortly after development started, most of the work has been done in ore. Shipment to the Douglas

the company's vertical shaft to find orebodies of which there is evidence on the upper levels.

BISBEE.—The mining properties of this district gave a four-day holiday, December 25, 26, 27, and 28, during which nothing but pumping and necessary repair work was done. The managers of the operating companies announced that this opportunity was given the men to enjoy Christmas. At the same time it gave the Copper Queen and Calumet & Arizona smelters at Douglas an opportunity to catch up on their ore stocks, as all bins at the Copper Queen were full and there was no storage for an additional ton of ore, while the C. & A. was in almost as bad a position.

SWISSHELM GOLD-SILVER.—Robert Randall, superintendent for the Swisshelm Gold-Silver company took the first car of 50 tons of silver ore from Webb to the C. & A.

smelter at Douglas, December 20. The property expects to ship steadily. It is situated 30 miles north-east of Douglas in the Swisshelm mountains, 12 miles east of Webb which is the nearest rail point. The ore is highly silicious, containing gold and silver, and the contract with the C. & S. smelter is understood to be advantageous to the company. The company is under the management of Ben Heney. Ore is freighted by wagon from the mine to Webb, a fairly good road being in existence. The adjoining property, the Great American, owned by Colorado capital, is starting development work preparatory to a period of activity, after being idle since 1884 when the last shipment to the Pueblo, Colorado, smelter showed returns of \$14 in gold and 119 ounces of silver. The recent activity in the silver market has encouraged the company to start active operation once more. The Great American ground, composed of four claims, was patented during the early mining history of Cochise county. The value of the ore deposition was not appreciated until 1905, when the original owners of the group now belonging to the Swisshelm Gold-Silver company, first acquired the property.

GLEESON.—A small force has gone to work on the Tejon mine belonging to W. H. McKittrick, who is expected to make a visit here shortly after the first of the year. His visit is taken to mean that operations will be opened on a larger scale. J. W. Bennie, manager of the Copper Belle properties of the Shannon company, has moved his headquarters here from Douglas and definite announcement of the company's intentions for future operation is expected to be made soon. Thomas Cowan, who owns several promising silver, gold, and copper properties, is shipping to the smelter at Douglas some good ore which he recently opened up.

COLORADO

CARBONERO PROPERTY SOLD.

TELLURIDE.—The heavy snowfall of the past month has curtailed ore shipments considerably. The railroad was blocked for a period of one week, from December 8 to 15. The Tomboy is now shipping concentrate from the new mill. The Smuggler Union Mining Co. is operating the new ball-mills at full capacity. A new brick assay-office is now under construction, replacing the one destroyed by fire.

OPHIR.—An important mining deal was closed when the ownership of the Carbonero passed to an Eastern syndicate, at a reported price of \$250,000. The mine has been a producer for the past 20 years, keeping up a steady production of ore averaging \$50 per ton. There are still large ore-reserves. Johnson, Klang & Troseth have leased the Santa Cruz mine in the Iron Springs district, from Painter, Toll & Brown, the owners of the property, and are making shipments of ore. The Santa Cruz carries an ore of a similar character to that of the Carbonero. The Silver Canon Mining Co., a Michigan corporation, is developing its property, and shipping ore. J. M. Belisle is disposing of some of his numerous properties in the vicinity, the Deadwood mine to a Michigan

company and the Crown Point to Gideon Baril. Mr. Ruutilla is starting development of the Favorite, having installed a gasoline hoist and will open up virgin ground through contract.

MICHIGAN

NOVEMBER COPPER PRODUCTION.

HOUGHTON.—The actual output of copper mines of Michigan for the month of November is practically the same as the output for October. In the larger mines there was little change. White Pine, a Calumet & Hecla subsidiary which re-opened in October, did not get its stride until November. La Salle and Superior, two smaller Calumet subsidiaries, dropped out altogether in the November figures. Limited work is being done at these properties, entirely exploratory in its nature, and the copper ore that is coming into the market is negligible.

Calumet & Hecla showed a decrease in output. This was not due to any change in general mining conditions but rather to the suspension of operations at one of the flotation plants. This production from the sandpile in the lake is becoming more and more a factor for the future consideration in the grand total of the Calumet & Hecla's record of output. Osecola continues to fall off a little month by month, in ore tonnage, in copper output, and in the quality of the production of the mine, the average being just over 15 lb. per ton. Ahmeek continues to be the best high-grade producer for the Calumet group.

The most remarkable demonstration of continued high-grade output is Mohawk. The showing of 24 lb. per ton in October was better in November when figures show 25.31 lb. This is the highest average that the Kearsarge lode is showing anywhere at this time. It is interesting to observe that the mine is maintaining a cost sheet which is creditable. Champion, Baltic, and Trimountain did not quite maintain their October showing in November. The figures follow:

Mine	Ore tonnage	Pounds per ton Nov.	Pounds per ton Oct.	Refined Nov.	Refined Oct.
Ahmeek	69,000	23.2	24.56	1,604,600	1,670,142
Allouez	18,000	18.2	19.86	328,100	337,828
Baltic	17,400	36	34	626,400	697,000
Calumet & Hecla	202,277	25	25	5,056,926	5,313,383
Centennial	7,000	14.4	16.9	101,000	114,500
Champion	37,000	40	40	1,480,000	1,640,000
Isle Royale	65,000	19.4	19.18	1,260,573	1,304,036
Mass Con	14,000	15	15	210,000	198,032
Michigan	5,000	20	23	100,000	112,000
Mohawk	40,828	25.31	24.34	1,033,322	1,062,279
Osecola Con.	50,000	15.3	16.14	904,714	938,252
Quincy	94,000	18	18	1,692,000	1,728,000
Trimountain	13,000	25	25	325,000	350,000
Victoria	6,750	16	14.4	108,000	110,130
Wolverine	22,567	14.53	16.62	327,970	399,249
Winona	9,000	15	15	135,000	95,000
White Pine	242,843	13,000

Winona will start working both 'heads' this week, due to increased ore production. Winona continues to add to the underground working force by employing men formerly working at the Mass Consolidated. The Quincy's new hoist at No. 2 shaft will be ready to operate by June 1, 1920, according to present plans. White Pine is putting on additional men, and the grade of ore quality is holding up to average.

NEVADA

GOLDFIELD PRODUCTION FOR 1919.—ACTIVITY IN EUREKA.

DIVIDE.—Eighteen inches of ore assaying \$600 and 16 in. assaying \$760 has been opened in a cross-cut driven west from the bottom of the 200-ft. Caldwell shaft of the Divide Extension, according to unofficial reports. The work on the 200-ft. level of the Divide Ex. has been the centre of interest in the district for a long period. A fault continuing from the upper levels was thought to be the hanging wall of the vein when first cut. Only minor assays were secured at this point and the work was continued, leading to the opening of the rich ore.

13-FT. PIERCE-SMITH BASIC-LINED CONVERTER IN THE GARFIELD SMELTER

The new shaft of the Belcher Extension, now slightly over 100 ft. deep, is in ore of an average value of from \$100 to \$125. No lateral work has been done to determine the width of the vein. The shaft of the Tonopah Divide, being sunk from the fifth, or 580-ft. level, is 630 ft. deep.

GOLDFIELD.—Preliminary estimates indicate that the production of the Goldfield district for 1919 was close to \$700,000. Latest estimates put a value of \$260,000 on the output of the Florence. Including bullion produced from the mill clean-up, the Consolidated output was \$263,300, most of this sum coming from the clean-up, as only 5165 tons of ore was milled to February 1, when the mines and mill were taken over by the Development company. A segregation of the \$263,300 is not available. The Development produced 4575 dry tons of a gross value of \$134,028, or a per ton value of \$29.30. The Jumbo Extension produced 132 dry tons of a gross value of

\$2914 as a result of work by lessees, and the output of the Great Bend was 85 tons of a gross value of \$2055. This gives a total of over \$669,000 and it is believed the final figures will reach \$700,000 because many of the important items in the Consolidated estimate are net. The Florence leases for 1920 have been let and an announcement from the management giving details is expected in a short time. The Florence Divide is expected to sign an agreement giving that company the most desirable part of the block mined last year. The Cracker Jack is understood to have secured a valuable part of the block.

SIMON DISTRICT.—A full face of silver-lead ore assaying \$12 has been opened in a cross-cut driven 80 ft. to the vein from the bottom of the 280-ft. shaft of the Simon Mina. A snow-covered road to the mine that is in poor condition makes economical operation difficult and it has been decided to suspend work until March.

ARROWHEAD.—Seams of rich silver-gold ore are being cut in a raise from the south-east drift on the 175-ft. level of the Arrowhead, indicating approach to the ore-shoot and proving that it rakes sharply in this direction. Fifteen inches of high-grade ore has been found beyond what was thought to be the foot-wall of the vein on the 100-ft. level. The average width of the ore at this depth is 8 ft. and the shoot has been opened for a length of 60 ft., with the face of the drift still in high-grade material.

EUREKA.—The Silver Lick group of 10 claims in the Adams Hill part of the district has been sold to Hayden, Stone & Co., of New York, for a price reported to be \$100,000, with a cash payment of \$10,000. The claims have been developed to a depth of 150 ft. through two shafts and it is said that they have heretofore produced \$250,000 worth of silver-lead ore. The Bullwhacker Consolidated Mines Co. has been formed to re-open the Bullwhacker and Silver West in the same part of the district. The company is controlled by the Eureka-Holly interests. The two groups, which adjoin the Holly on the strike of the vein, have been developed on a large scale to a depth of 300 ft. and have produced over \$400,000. The main shaft is 400 ft. deep. Work has been stopped in the 300-ft. winze from the 400-ft. level of the Croesus. Drifting has been started from the bottom of a 45-ft. vertical winze in the 'cave' orebody on the 200-ft. level, southwest of the Catlin shaft, and a promising shoot of rich ore is being opened. Ore of high grade is being found in a drift and raise on the 400-ft. level, far north of the shaft, where a search for the downward extension of the Dunderberg orebodies is being made.

UTAH

REVIEW OF UTAH'S PRODUCTION FIGURES FOR 1919.—DIVIDENDS FROM PARK CITY AND ALTA.

SALT LAKE CITY.—With the handicap of adverse economic conditions occasioned by the ending of the World War, mining activity in Utah during the past year has been greatly retarded. Added to the poor copper market conditions, the lead market for a large part of the year was in an unhealthy condition, so that the big lead producers naturally followed the copper producers and

curtailed operations. Coupled with the adverse market conditions, litigation involving some of the largest mines in the State, and a period of labor agitation in the Park City district, were factors in reducing ore production. All of the factors combined resulted in the production of metal in Utah dropping from a total value of \$86,047,597 in 1918 to approximately \$45,737,683 in 1919. The estimated gold production in 1919 is \$1,899,924, as compared with \$2,949,170 in 1918. The estimated value of 11,719,463 oz. of silver, assuming an average price of \$1.09 per ounce, would be approximately \$12,789,450, as compared with a production of 13,455,597 oz. during 1918, at an average value of \$1 per ounce. The estimated production of copper during 1919 is 127,092,221 lb., as compared with 227,169,630 lb. in 1918, which shows a curtailment of nearly 50%. The value of the 1919 production of copper is estimated at \$24,147,522, as compared with \$56,110,899 for the previous year. The lead production for 1919 is estimated at 124,213,073 lb., as compared with 167,008,224 lb. in 1918. Conditions at the close of 1919 are encouraging to the silver and lead producers of the State, but the condition of the copper metal market is such that there is no immediate prospect of the State's copper mines going back to a 100% basis of production. All of the smelters in the State operated throughout the year at reduced capacity. On January 1, 1919, the Utah Copper Co. discontinued operations entirely at its Boston mine at Bingham, and closed down its leaching plant and the greater portion of the Magna plant at Garfield. On March 1, the Magna plant was closed down completely, only a small force of men being kept for construction and remodeling work; all tonnage mined was treated at the Arthur plant during the rest of the year. All of the mills erected to re-treat tailing at Park City are now out of existence and the plants dismantled. The Midvale Minerals Co.'s plant at Midvale, built for the purpose of re-treating tailing from the United States concentrator, also suspended operations after encountering financial difficulties. The Judge electrolytic zinc plant at Park City was closed early in the year and did not resume operations.

EUREKA.—Operations at the Chief Consolidated mine were suspended from December 24 to 27, inclusive, during which time additional pumping equipment was installed. Three new centrifugal pumps have been received. A new 8-in. water column was put down the shaft. When centrifugal pumps were first installed the past summer, provision was made so the shaft for the discharge pipes was sufficiently large to carry water for four such columns as are now in use. The flow now is approximately 800 gallons per minute, being increased during the last few weeks by the water drained from the new shaft by the Plutus drift. Work in the No. 2 shaft of the Chief mine is progressing rapidly, with no water to contend with, and there remains but 60 ft. before connection will be made with the raise from the drift on the lowest level of the mine.

Operations at the Tintie Milling Co.'s plant are at a maximum. For the past few months the mill has been handling much of the low-grade product of the Chief

Consolidated, the Dragon Consolidated, and the various Jesse Knight properties. The plant is now treating about 300 tons per day with a chloridizing-leaching process known as the 'Holt-Dern Process', originally developed at Park City.

Ore shipments from this district for the week ending December 20, totalled 129 cars, a decrease of 14 cars from the previous week's shipments. A shortage of coal at several of the properties has caused some reduction. The Chief Consolidated shipped 36 cars; the Tintie Standard, 24; Dragon, 14; Iron Blossom, 12; Eagle & Blue Bell, 10; Mammoth, 6; Grand Central, 5; Centennial-Eureka, 5; Colorado, 5; Swansea, 4; Gemini, 2; Alaska, 2; Sunbeam, 2; Victoria, 1; Ridge & Valley, 1.

Directors of the Tintie Standard Mining Co. held a special meeting on December 22 and declared an extra dividend of 15c. per share, payable December 24. This, with the regular dividend of 8c., will make a total dividend of 23c. per share for the last quarter of the year. There are 1,175,000 shares of stock outstanding, so that the dividends for the quarter will total \$270,250, bringing total dividends for the year up to \$552,218, and the total to date \$1,234,674.

PARK CITY.—Discovery of a bedded deposit of high-grade carbonate ore, four feet thick, is reported from the Silver King Consolidated mine. It is some distance south of the bedding opened in September, and is surrounded by unexplored territory. It is said that the ore is of the same character as the carbonate produced by the bedding in the north end of the 'Electric Light' claim, which averages \$50 to \$60 per ton, net. The usual rate of progress is being maintained by the company in driving the Spiro tunnel, which is in more than two miles and will soon be under a prospect shaft on the 'Marconi' claim, where there are indications of ore. Beyond this point the tunnel will pass in rapid succession through the series of fissures famous for their productivity in the Silver King Coalition and the easterly workings of the Silver King Consolidated.

Shipments of ore from the camp for the week ending December 20 totalled 1978 tons, of which the Judge M. & S. Co. shipped 671 tons; the Ontario Silver, 548 tons; the Silver King Coalition, 505 tons; Iowa Copper, 55 tons; Naildriver, 55 tons; and Daly-West, 143 tons; total, 1978 tons.

ALTA.—At a meeting of the directors of the Cardiff Mining & Milling Co. on December 19, a dividend of 15c. per share was declared, payable December 24. This will call for the payment of \$75,000, and will bring the total dividends paid by the company up to \$800,000. The present dividend is the first paid the stockholders since October 1, 1918.

Through a deed just filed with the county recorder, two claims owned by the Tipperary Mining Co. become the property of the Emma Silver Mining Co. These two claims, the 'Revolution' and 'Mackay', cut into the property of the Emma Silver, and rather than have any difficulties in the future, the Emma company purchased the ground, and in so doing squared off their extensive holdings in the camp.

BRITISH COLUMBIA

AGREEMENT REPORTED BETWEEN OPERATORS AND UNIONS.

VICTORIA.—An agreement is reported to have been reached between the operators and the miners of District 18, United Mine Workers of America, which comprises eastern British Columbia and the Province of Alberta. The agreement reached covers an increase of 11% in the men's pay and also stipulates that only members of the U. M. W. of A. may work in the mines of District 18. G. Robertson, Minister of Labor, in discussing the situation said: "I have no statement to make regarding the 'One Big Union' other than that contained in my letter to Henry Beard in reply to a communication that he addressed to me. I feel that from the information contained in my reply the public will approve and endorse the course taken by the coal operators and the United

Miners' Association of British Columbia. The Texas Creek mine was opened in 1911 and taken over by the present company in September 1918. Since then the company has made cuts to 900 ft. and has taken out 16 tons of ore, half of which was shipped to Ontario while the remainder still is on the dump. All shares in this company are said to have been taken off the market.

That the Lorne and another of the operating properties of Cadwallader creek has been bonded by the Mining Corporation of Canada is reported on good authority. This corporation recently acquired the Pioneer mine on the same waterway.

STEWART.—The Alguvaquin Syndicate, of Belgium, has bonded the Northern Light group of eight claims from Charles and William Bunting, original locators of the Premier mine, the Woodbine group, the fraction owned

ON HOWE SOUND, BRITISH COLUMBIA

Mine Workers, and approved by the Director of Coal Operations for the purpose of preventing as far as possible a deliberate attempt, without cause, on the part of the O. B. U. to bring about a tie-up in the coal industry unless they were recognized. That, of course, is out of the question."

The main points in the Minister's letter to Henry Beard are that it is obviously impossible to recognize two organizations as having jurisdiction to negotiate wage agreements for the same workmen; that the United Mine Workers have a well established reputation for respecting and fulfilling agreements made; that the organization Mr. Beard represents has by its acts and utterances of its leaders indicated no tendency to respect or fulfill any contractual obligation, and that the O. B. U. as an organization was wholly unreliable and untrustworthy.

LILLOOET.—Attention has recently been directed to the property of the Index Milling & Mining Co., situated on Texas creek, 12 miles from Lillooet. This company claims to have the highest-grade molybdenite on the con-

tinental, assaying between 15 and 19%. The Texas Creek mine was opened in 1911 and taken over by the present company in September 1918. Since then the company has made cuts to 900 ft. and has taken out 16 tons of ore, half of which was shipped to Ontario while the remainder still is on the dump. All shares in this company are said to have been taken off the market.

That the Lorne and another of the operating properties of Cadwallader creek has been bonded by the Mining Corporation of Canada is reported on good authority. This corporation recently acquired the Pioneer mine on the same waterway.

STEWART.—The Alguvaquin Syndicate, of Belgium, has bonded the Northern Light group of eight claims from Charles and William Bunting, original locators of the Premier mine, the Woodbine group, the fraction owned

by David O'Leary and Charles Lake, and the Cobalt group of three claims, owned by John Hovland. A considerable part of this property adjoins the Premier. There are nine veins on the Northern Light group that have characteristics similar to those on the Premier, while on the Woodbine a body of milling ore has been uncovered 100 ft. in length and 70 ft. in width. W. A. Meloeche, who is acting for the Belgian syndicate, has let a diamond-drill contract to Lynch Brothers, of Seattle, who will put three drills to work as soon as the season opens next spring. W. B. Tanner has acquired the property adjoining the Forty-Nine group, and is forming a syndicate to develop it. A vein of milling ore 27 ft. wide is reported from the New Alaska, on the United States side of the boundary. A Vancouver company is being formed to take over the property adjoining the New Alaska from J. Sehwerter, Angus McKenbie, and E. Borson. The new government road from Stewart to Hyder has been completed. Though it is only a little more than two miles long, it has been a costly and difficult piece of construc-

tion, more than half of it being trestle and rock work around a steep bluff. Besides connecting the two towns, the road connects the groups of mines in the Salmon River and Bear River valleys, making the mines readily accessible to both of the towns.

GILTSWOOD.—The Bell mine, at Beaverdell, which has been shipping monthly two cars of copper ore assaying 100 oz. silver per ton, recently shipped a car of ore that assayed 502 oz. per ton in silver. After all charges had been paid the car returned the shippers \$17,000.

TRAIL.—The Consolidated M. & S. Co. has cleared the refuse from the fire at the copper-ore crusher, and will erect a much larger plant in its place. The new building will be of reinforced concrete and will cost in the vicinity of \$50,000. The company is doubling the capacity of its machine-shop by the addition of a new wing, having a floor-space of 42 by 100 ft. T. Hopkins, who has returned from England, where he had charge of munition work, has been made superintendent of the electrical work at the smelter. The extremely cold weather has caused a shortage of water, and the Consolidated company has had to close its concentrator.

ANYOX.—The Granby company blew-in an additional furnace last month, and is now smelting 80,000 tons of ore per month, an increase of more than 25%.

CARIBOO.—Robert Bryce and associates, who hold an option on the Independent and the Imperial groups, on Proserpine mountain, have secured an option on the Dufferin group from David Moore. Mr. Bryce has driven between 200 and 300 ft. of tunnels on the former properties, as well as a considerable amount of open-cutting, and is anxiously awaiting the arrival of two diamond-drills that are on their way to the property.

ONTARIO

MOLYBDENUM IN QUEBEC.—GOOD OUTLOOK IN COBALT.

TORONTO.—The report of the invention by John O. Arnold, Professor at Sheffield University, England, of a new steel of superior hardness, molybdenum being one of its constituents, has created much interest in Ontario mining circles. During the War molybdenum was much in demand and several important deposits of molybdenite, principally in the Ottawa valley, were developed. Owing to the employment of tungsten as a hardening metal the demand for molybdenum fell off, and since the War there has been no production. Simultaneously with the announcement of Prof. Arnold's invention comes the report of the finding of large deposits of molybdenite in Pontiac county, Quebec. Should the new process prove successful a revival of the molybdenite mining industry on a large scale is anticipated.

The Lignite Utilization Board, appointed by the Canadian government to install and operate a plant in western Canada for the briquetting of lignite coal, of which there are large deposits in Saskatchewan, reports that the plant will be in operation by next August with a capacity of 30,000 tons of briquettes per annum. The Board, which has made an exhaustive examination of the process, visiting many plants in the United States, states that

briquettes can be produced equal to anthracite in heat-value and keeping qualities, and sold for about \$9.40 per ton in Winnipeg. The plant will be situated near Estevan, Saskatchewan. Though the output as compared with the requirements of Manitoba and Saskatchewan will be but a 'drop in the bucket', it is hoped that the project will considerably relieve the fuel situation by proving the commercial feasibility of the process and inducing private capitalists to engage in the industry.

LARDER LAKE.—Contracts by the Associated Goldfields for 5000 ft. of diamond-drilling are approaching consummation. The work has been successful in indicating some rich ore and large bodies of low-grade material. Underground work is proceeding on six faces all in ore. A high-grade shoot 25 ft. wide developed on the 500-ft. level of Block B has been encountered on the 400-ft. level. The company is increasing its working forces. The Larder Swastika Prospectors Association has been organized in the interests of this district and the adjoining area of Swastika. It has actively taken up the transportation question and is urging the Provincial government to construct a railroad to the camp.

COBALT.—The development of a large amount of high-grade ore during the past several months at the Nipissing, as well as recent discoveries of rich ore-shoots on such properties as the Crown Reserve, Beaver Consolidated, and Temiskaming gives promise of a moderate increase in the output from Cobalt during the next few months. The Nipissing continues to produce at the rate of close to \$12,000 daily. As a consequence of having accumulated a surplus of some \$4,300,000 the company will disburse a bonus of 5% in addition to the regular January dividend of 5%, the total disbursement amounting to \$600,000.

According to authoritative advice the Crown Reserve is producing silver in greater volume during the current month than for several months past. Some of the ore recently encountered is equal in richness to the best ever found in the mine. A considerable tonnage containing several thousand ounces per ton has already been prepared for shipment.

The Temiskaming Mining Co. after a lapse of some two years has resumed dividend disbursements and in January will distribute 4%, amounting to \$100,000. The McKinley-Darragh is producing at the rate of 1918, when 904,543 oz. was the output. The oil-flotation plant is still being operated but will probable close some time in February, to be shut down until May. In a semi-annual report just issued by the Peterson Lake Mining Co. it is stated that adequate finances have been secured with which to conduct the contemplated exploration and development work. A recent shipment of ore netted the company \$13,727. In addition to this, the report mentions the sale of 385,000 shares of treasury stock at 15c. per share.

The Cobalt mining companies are giving more attention to the Gowganda and Elk Lake silver-bearing area where promising results continue in the exploration of numerous prospects.

ARIZONA

Kingman.—Messrs. Downer, King, and Clark of Tonopah have taken over the Estaleah-Cerbat Silver Mining Co.'s property in the Cerbat district on behalf of the Divide Mining Co. Extensive development work is being planned. A considerable amount of development was done by the old company and a large tonnage of lead-silver ore was shipped from the upper workings, some of the shipments assaying 68% lead, \$30 gold, and 35 oz. silver.

A 4-ft. orebody on the 300-ft. level of the Senate silver mine has been opened. This development proves the continuity of the orebody to that depth. The vein varies in width from 3 to 9 ft., and a large tonnage of ore was taken from the surface years ago. The 300-ft. level of the Senate corresponds to the 400-ft. level of the Hackberry Consolidated from which ore is being shipped containing 200 to 300 oz. silver per ton.

The drift on the 300-ft. level of the Telluride mine at Oatman is now in ore assaying \$30 in gold over a width of 30 in. To date a length of 100 ft. has been proved and the ore continues to improve as progress is made.

Mayer.—The Rebel and Kicker claims adjoining the Gladstone have been purchased by the United American Copper Co. These claims were owned and operated by the Amalgamated Copper Co. in the 'eighties. They have been leased from time to time, development having been carried to the 200-ft. level. A large number of profitable shipments have been made. A power plant, hoist, and compressor are to be installed at once.

The Arizona Copper & Mining Co. is installing newer and larger equipment on the Pentland mine. Development work has now reached a depth of 800 ft. and preparations are being made to mine and ship ore from the 500 and 600-ft. levels.

CALIFORNIA

Nevada County.—The Penn-California Mining Co., of Pittsburgh, Pennsylvania, owner of 15 properties approximating 1000 acres, is still driving its tunnel into the hill, having already penetrated 1000 ft. of hard granite. Another 200 ft. will probably be necessary before raising into the ore-channel. The tunnel was surveyed by E. C. Uren, and is 5½ by 7 ft. in the clear with a 6% grade. A 15-stamp mill has been completed near the tunnel outlet. The officers of the company are: Charles L. Walther, president; A. W. Hoge, first vice-president and general manager; W. H. Ketchum, second vice-president.

Sierra County.—It is reported that James F. Hunt has organized a company to operate the Oxford mine near here, and plans to start work at once. A tramway will be built to the Gold Bluff mill, where the ore will be crushed. Two Gibson mills will be installed to re-grind the tailing from the mill, and take the place of concentrators. Work will begin at the apex of the vein.

COLORADO

Mayday.—Fred Brandiger and Geo. W. Avery have opened up a new orebody at the Idaho. The vein is said to be three feet wide and to assay on an average \$50 per ton in gold.

A carload has been taken out ready for shipment to the smelter.

The Idaho shut-down four years ago, when its ore was said to have been exhausted, after a record as a steady shipper of high-grade ore. Several carloads shipped from the dump during the past summer assayed from \$32 to \$50 per ton. The Idaho has produced approximately \$2,500,000.

IDAHO

Coeur d'Alene.—The Montana-Idaho Copper Co., engaged in a large development enterprise near Adair, has suspended operations because of a shortage of water, according to W. J. Kirby, secretary-treasurer. The company has operated continuously for the last four years and will resume when conditions permit.

The Caledonia Mining Co. has declared its usual monthly dividend of \$26,050, according to Stanly A. Easton, president. This is at the rate of 1c. per share on an issue of 2,605,000 shares. Payment will be made January 5. The forthcoming payment will increase the total of disbursements to \$4,011,700.

The Consolidated Interstate-Callahan company shipped 5,825,889 lb. of zinc concentrate in November last. It shipped 2,164,908 lb. of lead concentrate and 20,017 oz. of silver in the same month. This showing was due to improved methods of handling and the oil-flotation system of metal recovery, according to report.

Latah County.—Five feet of chalcopryrite ore, averaging 10% copper, has been struck by the Merger Mining Co. in a shaft 30 ft. deep, according to E. R. Northrup, secretary. The vein at this point has been cross-cut 11 ft. without disclosing the foot-wall. Six feet of the vein toward the foot-wall will average 2% copper.

Shoshone County.—"In recent months we have put many additional tons of ore in sight by drifting on the vein, principally on the 700-ft. or old No. 2 tunnel level," is the statement of Henry H. Armistead, president of the Armistead Mines. "On this level the vein has been opened at points 1600 ft. apart principally by drift, but partly by cross-cuts. The campaign for the winter includes drifting on the vein at points north and south from the raise and a continuance of the raise for 150 ft. above its top. The raise is about 600 ft. long and connects the No. 3 and 2 tunnels."

MONTANA

Butte.—The Anaconda Copper company has declared a dividend of \$1 per share, payable February 24 to stockholders of record January 17.

NEVADA

Hawthorne.—We are informed by John B. Platts, superintendent, that a large body of minable ore has recently been opened in the old Sunrise mine, now called the Silver Dollar, situated about 20 miles south of Hawthorne. After sorting and shipping some high-grade ore 40 years ago the mine was closed down and allowed to cave. It was not re-opened until this year when the Oro Zona Mines Co. acquired the property and cleaned out the old workings. Cleaning out an old mine is a risky undertaking because the traditional rich

ore in the bottom is seldom there. In this case the operators were agreeably surprised to find a large body of paying ore almost untouched except for the development work. The ore contains gold, silver, and some lead, is 6 ft. wide, and the shoot is nearly 1000 ft. long. The shaft is a little over 100 ft. deep with good ore in the bottom.

Pioche.—The Prince Consolidated Mining Co. is speeding the sinking of the new shaft to the orebodies below. For the past two weeks an average advance of 5.8 ft. per day has been made in the deepening of the big working shaft, which has now reached a total depth of 475 ft. The water-level is still 70 ft. deeper, but at the present rate of progress it should be reached soon. A large station will be cut at the water-level to accommodate the pumps and other necessary equipment to continue work. The installation of the sterling boilers will be completed by January 15. All the necessary adjuncts to the pumping and power installations should also be completed by that time. A sub-track bin for coal is being built and the coal will be transferred from this track-bin to the big storage-bin, situated at the boiler plant, by a wide conveyor-belt.

OKLAHOMA

Quapaw.—The Charlotte Lead & Zinc Co. is just completing a new 150-ton mill on its lease two miles east of Quapaw, and will begin operation early in January. The mill is of 150 tons capacity, equipped with gas engines. Gas and steam equipment have been furnished for the underground work.

Two shafts have been sunk into ore, which was encountered at \$5 ft., being about equal in lead and zinc value. I. M. Holcomb of Oklahoma City is president of the company. The Lead Boy Mining Co. is preparing to resume operations at its Lead Boy mill, two miles east of Quapaw, immediately after the first of the year. The mill has been closed down for the past three or four months, but has been cleaned up and put in first-class condition for steady work in 1920. It is a 150-ton plant.

WASHINGTON

Spokane.—Special interest attaches to the annual convention of the Northwest Mining Institute in Spokane, February 16-21, as the 'flu ban' prevented the annual gathering in 1919. An exceptionally good program has been arranged, including special days for Idaho, British Columbia, and Washington.

Work of a permanent character has been done on the Gladstone Mountain mine, Northport district, recently, according to Dan D. Dodd, superintendent. The company has 100 tons of clean ore on the dump.

L. Oriard and associates of Marshall are working the Goldenrod mine near Chesaw and will ship their first car of ore shortly. This ore averages \$40 in gold, \$11 in silver, and \$3 in lead, and is hauled six miles to the railroad and then shipped to the smelter at Northport.

J. A. MacLean, owner of the Roosevelt mine on Copper mountain, near Chesaw, has closed a contract with the Northwest Magnesite Co., Chewelah, to ship 2000 tons of magnetic iron ore from his property there. Delivery to the Chesaw spur will be made by two motor-trucks handling five tons each per trip.

The Electric Point Mining Co. expects to make 1920 the banner year in volume of production. The best year of the Electric Point was 1917, when it shipped 16,310 tons and after disbursing \$158,700 in dividends had a surplus of \$200,000. Since 1917 the company has installed a tramway more than two miles long that eliminates a hard and dangerous wagon haul of several miles. The tramway will handle 200 tons per day with ease and can handle 500 tons daily under pressure, according to a recent statement of the builders.

Personal

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Jay P. Graves is at Pasadena.

R. C. Gemmell is in San Francisco.

F. A. Goodale has gone to Australia.

W. J. Elmendorf was recently at Sandon, B. C.

Charles A. Banks, of Vancouver, is on his way to London.

Theodore J. Hoover has returned to Palo Alto from New York.

L. W. Lemox has returned to Cripple Creek by way of Los Angeles.

F. W. Holler is superintendent of the Surf Inlet mine in British Columbia.

W. D. Thornton was here from New York during the Christmas holidays.

S. M. Levy, manager for the Calaveras Copper Co., has returned from New York.

Charles F. Willis has become editor of the 'Arizona Mining Journal', published at Phoenix.

G. M. Colvocoresses, manager of the Humboldt smelter, near Prescott, Arizona, has been in New York.

Andrew W. Newberry has opened an office at 66 Broadway, New York, as consulting mining engineer.

Fred. B. Meehling, of Tonopah, was in San Francisco on his return from the Yale district in British Columbia.

W. W. J. Croze, manager of the geological department of the Oliver Iron Mining Co., at Duluth, Minnesota, has gone to Brazil.

P. G. Beckett has been promoted to general manager for the Phelps Dodge Corporation, with headquarters at Douglas, Arizona.

Norman N. Bye, superintendent of the Silver King Consolidated mine at Park City, Utah, spent the holidays at Los Angeles.

Arthur W. Jenks has just returned from Oregon and Idaho, where he has been making a series of examinations for Portland clients.

Herbert S. Shuey, secretary to the Merrill Company, of San Francisco, was married on December 26, to Miss Florence McAvoy, of Boise, Idaho.

J. C. Lane, superintendent of the Kennecott Copper Corporation's milling plant in Alaska, is visiting metallurgical plants in Utah, Nevada, and Arizona.

Summer S. Smith, of the U. S. Bureau of Mines, was in San Francisco on his return from Anchorage, Alaska. He is now examining coal-cleaning plants in New Mexico.

Charles W. Adams, recently appointed general manager of the East Helena plant of the A. S. & R. Co., was married to Miss Mary Crowley at Salt Lake City on December 26.

J. Harry Hughes, of Mobile, Alabama, who served in France with the Rainbow Division, has become assistant superintendent for the Ranier Mines Corporation, at Wenden, Arizona.

E. W. Engelmann has been appointed to the position of consulting research engineer for the Utah Copper, Chino Copper, Ray Con. Copper, and Nevada Con. Copper companies, with headquarters at Salt Lake City.

Charles Keith Blackwood, vice-president, assistant treasurer, and a director of the Sullivan Machinery Co., died in Chicago on December 14. His sound financial judgment, keen foresight, and executive ability, had been important factors in the Sullivan company's growth during the past seventeen years, where he was a valued associate and loyal friend.

THE METAL MARKET

METAL PRICES

San Francisco, December 30

Aluminum dust, cents per pound	65
Antimony, cents per pound	10.00
Copper, electrolytic, cents per pound	13.00
Lead, pig, cents per pound	7.75-8.75
Platinum, pure, per ounce	\$150
Platinum, 10% iridium, per ounce	\$180
Quicksilver, per flask of 75 lb.	\$85
Spelter, cents per pound	10.00
Zinc dust, cents per pound	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

December 30.—Copper is active and higher. Lead is strong and advancing. Zinc is active and higher.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

There have been persistent rumors that "something was being done" to improve the European exchange situation. These rumors have been lent color by a slight recovery in the sterling rate during the last few days. But investigation fails to uncover the existence of any new steps along this line, other than those already planned or outlined and which are being held in abeyance pending formal termination of the War. The Far Eastern exchange problem is less difficult and action intended to stabilize rates in the Orient are being taken.

Three million silver dollars were shipped from San Francisco to China on Christmas Day. Consignment is being made on joint account by the International Banking Corporation, Park Union Foreign Banking Corporation, and Ash Banking Corporation. It is the first shipment which these institutions have forwarded to the Orient under the arrangement they have recently entered into with the Government for the purpose of stabilizing Far Eastern exchange and conserving this country's supply of gold. In accordance with the terms of agreement, the silver dollars have been procured against the tender of current funds from the free supply carried by the Government in its general fund. That the silver pieces are being sent intact, without first being melted down into bars, is due, for one thing, to the approach of the Chinese new year, which begins February 1. This date in the Chinese calendar is the general settlement period, and the Chinese money market usually experiences considerable hardening.

The present shipment is not the first consignment of silver dollars to China. Before the Government embarked on its present policy of selling silver dollars to the three institutions named above, an aggregate of 12,000,000 silver dollars had been forwarded to China on strictly private account, 3,000,000 on November 25 and 9,000,000 on December 10. Among the shippers of these earlier consignments were the International Banking Corporation, which initiated the movement, the Hongkong & Shanghai Bank, the Equitable Trust Co. and the Chartered Bank of India.

A rather interesting feature connected with these consignments is the fact that the silver dollars were obtained from the San Francisco sub-treasury against the payment of current funds. Except under the plan now in operation, silver dollars are ordinarily procured from the Government only against the presentation of silver certificates. But after some negotiations with the Washington authorities bankers succeeded in securing silver dollars, against the tender of current funds, from the stock earned by the general fund. This explains the reduction in the amount of free silver dollars held by the Government from 67,000,000 in the latter part of November to 52,000,000 on December 11.

Large amounts of silver bullion have also been forwarded from this country to China during the past several weeks. Bankers are inclined to anticipate a considerable increase in the movement, if not a total cessation, in the not distant future. Future dollar exchange in Shanghai, for delivery about the first of February, which is usually the form of remittance to this country, purchased in Shanghai against shipments of the white metal from the United States, is already quoted below the export parity, and with the approach of the Chinese new year, it would not be surprising if a further decline should occur in the rate, particularly if silver continues to maintain its present strength in this market.

Foreign exchange quotations on December 30 are as follows:

Sterling, dollars: Cable	3.79 1/2
France, francs: Cable	3.78 1/2
Germany, marks: Demand	9.33
Italy, lire: Demand	9.31
Spain, pesetas: Demand	7.60
Sweden, kronor: Demand	2.15

Eastern Metal Market

New York, December 23.

All the markets are generally quiet as is usual at this season. Sterling exchange values still are a prominent factor in determining prices of some metals.

The copper market is very quiet but steady.

Tin prices fluctuate with the changes in the pound sterling. Buying has been lighter than for some weeks.

Lead is the strongest of all the markets and prices are still advancing.

The zinc market has turned quiet and prices are slightly easier but steady.

Antimony is quiet and unchanged.

IRON AND STEEL

The end of 1919 witnesses steel mills still guarding against overloading their books. Some companies which have been refusing business since the beginning of the coal strike now have capacity open for the first quarter of 1920, but the element of cost uncertainty still exists as an undetermined factor. Quoting high prices has been purposely done to discourage business. Semi-finished steel is hard to obtain. Steel and iron production in the leading centres varies but little from that of recent weeks, the coal supplies not having increased to the extent indicated by reports from some mines. Expectation of considerable railroad business after January 1 is general and for rails alone orders running up to 800,000 to 1,000,000 tons are not improbable in 1920. Output of automobiles is still limited by the non-delivery of sheets and one large Detroit company has had to curtail 50%.

COPPER

The market has been quiet but sales are reported to have been fairly substantial, some of them to foreign countries. Japan has been again a heavy buyer. Prices have undergone little change. Electrolytic copper for December and January delivery is steady at 18.75 to 19c., New York, with Lake copper at about 19 to 19.25c., New York. One large producer is reported as stating that sales in the last 60 days have been exceedingly large, while another authority asserts that between 250,000,000 and 300,000,000 lb. were contracted for this month, of which about 50,000,000 lb. is for export. Domestic business has been largely for December and first quarter of 1920, although some business is reported to have been booked for second quarter. Besides Japan, purchases have been made by Great Britain, France, Italy, and some by Germany, with the Scandinavian countries also buyers.

TIN

Conditions have changed but little from those obtaining a week ago. The market has been generally quiet. Less metal has been sold than during last week but price fluctuations have been erratic. Sterling exchange continues the predominating factor. Prices for spot tin are changing each day with the variations in the rate of exchange. As the result of a higher value to the pound sterling yesterday and also a much higher London market, spot Straits tin was quoted yesterday at 55.50c., New York. In London spot Straits was £325 5s. per ton, or an advance over the previous day of £2 17s. 6d. With the value of the pound at \$3.80 this makes the London price of spot Straits about 55.25c. per lb. and not far from the American market. Because of the difficulty in obtaining future exchange there has been no buying or even quoting on future shipments. American pure tin is quoted at 54.25c. with the 99% grade at 54c.

Arrivals thus far this month have been 4928 tons, of which 1190 tons is credited to Pacific ports. The quantity afloat is 3175 tons.

LEAD

"Exceedingly strong"—says a leading lead broker. It is the strongest of any of the non-ferrous metals. On December 18 the American Smelting & Refining Co. again advanced its price from 7 to 7.15c., New York, and 6.85 to 6.90c., St. Louis. The tendency is decidedly upward and, while some regard the price as too high now, it is acknowledged that it may go higher. A pronounced scarcity as well as a good demand are two of the causes of the present high prices and there is also the factor of higher values abroad as well as less metal for importation. The London market yesterday was £43 15s. per ton for spot lead or £20 higher than six months ago. The outside market, which at present represents values, is quite a little higher than the Trust. Today lead has sold as high as 7.35c., New York, or 7.10c., St. Louis, which we quote as the market. Production generally is reported as better and it is expected that this will be felt in lower prices by March 1920.

ZINC

Despite the fact that there has been quite a lapse in foreign buying and no increase in domestic demand, which has been light for some time, the market remains steady. The strength is evidenced by the fact that producers are comfortably sold up as far ahead as desired and are not pressing the market. The speculative position is also very favorable. Prime Western for early and first quarter delivery is quoted at 9.30c., St. Louis, or 8.65c., New York. The London market has advanced very recently but owing to the wide changes in sterling exchange buying for British account has been checked. The London market was quoted yesterday at £53 15s. per ton, which is about 9c. per lb. at the present value of the English pound in American dollars.

ANTIMONY

No changes are recorded. Wholesale lots for early delivery are quoted at 9.62½c., New York, duty paid, with demand light.

ALUMINUM

For the best grades of virgin metal, 98 to 99% pure, quotations are nominal at 32 to 33c., New York, for wholesale lots for early delivery.

ORES

Tungsten: The market is dead and is expected to remain so until early in 1920 at least. Quotations are purely nominal at \$7 to \$15 per unit, depending on the grade of ore. Business in ferro-tungsten, if any, is probably a matter of negotiation as no open market quotations are heard of. Values are probably around \$1 to \$1.15 per lb. of contained tungsten.

Molybdenum: Conditions are unchanged and quotations are nominal at about 75c. per lb. of MoS₂ in regular concentrates.

Manganese-Iron Alloys: American producers of ferro-manganese have advanced their quotations to \$130, delivered, or \$10 over the recent price at which a heavy business was done. The only British alloy known to be available is 1000 tons for second quarter at \$120, seaboard. None of this is reported sold thus far, it having been before the market a week ago. Another British seller has a nominal authorized asking price of \$125, seaboard. Spiegeleisen is strong but quiet at \$40, furnace.

PRODUCTION of gold and silver in this country decreased in 1919, according to the preliminary figures issued by the U. S. Geological Survey and the Mint. The output of gold was \$10,157,900 less than in 1918, but California retains the lead, with 840,758 ounces; Colorado is second, and Alaska is third. The output of silver was 12,524,943 ounces less. Montana is first with 14,940,527 ounces; Utah is second, and Nevada is third. These statistics confirm our anticipations.

SEVERAL letters have come to us, apropos of an editorial paragraph in our issue of December 27, asking whether the premium on gold in London is being paid by the British government or by manufacturers. The fact is, of course, that the lifting by the Government of its embargo on the free sale of gold has given play to the force of an increasing demand from those needing the metal in art and industry. A recent letter states that the premium has risen 25%, much to the benefit of the South African, Australian, and Indian gold mines, all of which, naturally, sell their gold in London.

WE are informed that Mr. Van. H. Manning, Director of the U. S. Bureau of Mines, has made an arrangement with the Governor of Colorado whereby \$10,000 will be spent under the direction of the Bureau in making investigations into the oil-shale industry of Colorado. This investigation is to be placed in charge of Mr. Martin J. Gavin, refinery engineer of the Bureau, and will be conducted at Boulder, where a laboratory and office will be furnished by the University of Colorado. The main purpose of the investigation will be to provide the data necessary for the development of a commercial process of retorting oil from the shale and for refining the product.

COPPER sales during 1919 were disappointing, but the outlook today is better than it was at the beginning of last year. Then the surplus was estimated at a billion pounds, but this included the metal in transit to the refineries, so that 650,000,000 pounds would be a fairly correct figure. During the first four months of 1919 the absence of sales and the accumulation of output caused the surplus to rise to nearly a billion pounds, and prospects looked black. They remained cheerless until the last two months of the year, when about 250,000,000 pounds was sold during five weeks, for delivery during the first quarter of this year. Thus deliveries of copper

in 1919 did not equal the output and the real surplus today is larger than it was a year ago. However, the outlook is much improved, for the output from the mines has been decreased considerably, while heavy sales have been made for forward delivery. The demand from abroad is more lively and if only the treaty of peace can be ratified there will be a large expansion of export business.

ACCORDING to information from New York, the American Metal Company has taken over the business of L. Vogelstein & Co., which includes the copper refinery at Chrome, New Jersey. At the recent sale of shares held by the Alien Property Custodian, a large block of stock was purchased by Mr. Ludwig Vogelstein. Other purchasers were the Cerro de Paseo Copper Company, J. Horace Harding, Louis T. Huggin, Charles D. Barney & Company, and others connected with the Cerro de Paseo company. Mr. Vogelstein has been elected a vice-president of the American Metal Co., a fact that suggests how the German element is expelled through one door only to enter through another.

WHETHER the United States will make a large loan to the European nations, or not, is a question to be decided by Congress, not by Mr. Hearst, who belabors the issue with a lot of mis-statements and exaggerations intended chiefly to excite animosity against Great Britain, where he received a personal slight that has made him vindictive ever since. Apparently international trade is in a bad way, for lack of credits, and Great Britain is taking the lead, in behalf of Europe, in arranging for a large scheme of reconstructive finance, such as will prevent certain parts of the war-devastated countries from utter destitution and industrial collapse. The President and Congress of the United States will do what seems best to them, weighing our own interests first and then those of the less fortunate nations. It is a big subject, and it ought to be studied, not with narrow-minded meanness, but wisely and generously.

ABUDGET is essential to the efficient conduct of any enterprise. A schedule of expenditures, systematically proportioned among the various departments, according to their respective requirements, and with due regard to the total funds available, is necessary. Many households, every efficient business, and nearly every government except that of the United States regulates its

financial affairs by means of some sort of budget. Our method of congressional appropriation is crude, haphazard, unscientific. Only the extraordinary capacity of this country to supply revenue has enabled our income to keep pace with our steadily increasing expenditures. Economists agree that a financial policy so devoid of system as that of our government would speedily bankrupt the soundest railroad corporation. The theory of the budget is to provide the funds needed, but to detect proposed waste and prevent appropriations for non-essentials. Actual experience has proved that the plan operates in practice just as it works out in theory; intelligent people perceive, and fair-minded congressmen concede, this fact. And still we have no real budget, simply because certain alleged 'statesmen' in Congress feel that such a departure would rob them of some of the authority attaching to their position. One solution is to send down to Washington more men of a type different from the average politician. The pompous congressman that nourishes his own personal conceit in constant fear that his individual power may be merged by co-operation with his colleagues is a stumbling-block to efficient government. The acceptance by engineers of their obligation as good citizens to interest themselves in elections will be one step toward the establishment of a national budget.

ON December 12 a jury in the District Court of Southern New York found a verdict of guilty against Harry Lefkovits and R. V. Stuart for use of the mails to defraud, by selling stock in a wild-cat mining company, called the United Magma Mines. This company was hatched during the copper boom in the early part of 1917, but no work was done until after the Government started an investigation preparatory to an action for fraudulent use of the mails. The trial, which began on November 19 last, occupied three weeks. Mr. Louis Lefkovits, brother of the other Lefkovits, was acquitted, and so also was the company itself, the Judge dismissing the case against these two because no definite evidence was available to show that Mr. Louis Lefkovits knew that his brother in New York was selling stock. The locating of the claims in Arizona was done by one brother, while the other did the share-peddling. This brought in \$100,000, of which only \$12,000 went into the company's treasury, the difference presumably being loot. Between April 1917 and January 1919 the only work done on the property was the location work required by law. Mr. Louis Lefkovits obtained permission from the State Corporation Commission of Arizona to sell 200,000 shares at 25 cents, his commission being 5 cents per share. He sold this stock to his brother in New York for 50 cents per share, making the commission 30 cents. Louis claimed that he sold the stock outright to Harry, so that the latter could do as he pleased, but this version of the deal was not accepted by the jury. The property consisted of a string of claims so located that one end of them adjoined the famous mine of the Magma Copper Company in Arizona. The circulars, issued for the pur-

pose of selling stock, were full of the usual iridescent descriptive matter, speaking of a "gigantic orbbody" that was to be opened up immediately, if not sooner; they asserted that the wild-cat had "all the earmarks" of a great copper mine, such as the Magma, of course; and talked vaguely but magniloquently about "a policy of vigorous development". It is interesting to note that the promotion stuff was written by Stuart, formerly in the office of George Graham Rice; also that a stricter Blue Sky law is being demanded in New York.

The Industrial Conference

Last week we gave the gist of an important pronouncement by Mr. Hoover on the subject of national economies; since then we have read the report of the Industrial Conference appointed by the President for the purpose of devising suggestions looking toward a method for adjusting industrial disputes. To the 'Sacramento Union' we are indebted for the full text of the report, and we congratulate the editor, Mr. Ben S. Allen, on his enlightened enterprise in giving his readers an opportunity to study such an important document *in extenso*. Of course, it is important; nothing today so deeply concerns the welfare of the United States as some means for checking the succession of strikes that continually interrupt the production of the necessities of life, and undermine the very foundations of democratic institutions. The Conference was convened at Washington on December 1; it issued this preliminary report on December 28 in order to invite discussion before re-assembling on January 12, when it will give respectful consideration to any constructive criticisms that may be forthcoming. The report starts by saying that the purpose of the Conference at this time is to devise machinery for the adjustment of disputes, not to discuss the causes of them. It recognizes the human element in the problem. "Our modern industrial organization, if it is not to become a failure, must yield to the individual a larger satisfaction with life." The complexity of modern industry has tended to kill the spirit of human fellowship; the idea of mutual responsibility has been insufficiently developed. Our human relations must be adjusted to our economic interdependence. The right relationship must be encouraged deliberately. "Not only must the theory that labor is a commodity be abandoned, but the concept of leadership must be substituted for that of mastership." Until the growth of a better relationship between employers and employees, it becomes necessary to devise methods for retarding or preventing disturbance by providing machinery for the adjustment of differences. For this purpose the Conference suggests the establishment of tribunals so organized as to act promptly and impartially. On these tribunals the public must be represented in order to safeguard the larger interest of the community, as well as those of the employers and of the employees. "The plain fact is that the public has long been uneasy about the power of great employers; it is becoming uneasy about the power of great labor organizations. The community must be as-

sured against domination by either." This assurance can be obtained without discriminating against the organizations of either side in the dispute, labor or capital. The right of association on either side must not be denied. Therefore the Conference proposes the creation of a National Industrial Tribunal, which is to consist of nine members appointed by the President; three to represent the employers are to be nominated by the Secretary of Commerce, three to represent the employees will be nominated by the Secretary of Labor, and three will represent the public. This tribunal is to act as a board of appeal; its decisions must be unanimous, but provision is made for publishing majority and minority reports when no agreement is attained. The chief work of pacification will devolve upon regional boards of inquiry and adjustment. For this purpose the country will be divided into twelve regions similar to those established under the Federal Reserve system. In each region the President appoints a chairman, representing the public interest, for a term of three years, with eligibility to re-appointment. In case of an industrial dispute within any region, the chairman will ask each side to select a representative, under rules and regulations laid down for the purpose. The chairman then selects two employers and two employees from two panels previously prepared by the Secretary of Commerce and the Secretary of Labor, respectively, after conference with the employers and employees in the region. The two representatives first selected by the chairman will be entitled to a specified number of peremptory challenges of the names selected by the chairman from the respective panels. Those thus selected, plus the two representatives, with the chairman, will constitute the regional board of adjustment. The appointment of representatives of both sides will constitute an agreement to continue the status of the industry as it existed before the dispute arose, pending an effort at adjustment. Then comes the hearing of evidence by the Board for the purpose of a decision. Such decision must be unanimous; if not, it must be referred to the National Tribunal, unless, by unanimous vote, an umpire is chosen by the Board. If either side refuses to make use of this machinery for settling the trouble, and fails to select a representative, then the chairman is authorized to organize a board of inquiry, by selecting two employers and two employees from the respective panels, together with the representative of either side that may have agreed to submit the dispute to the Board. If both sides fail to choose a representative, the Board will consist of the chairman and the four panel members only. Any decision given by the board of adjustment, by an umpire selected by it, or by the national tribunal will have the full force and effect of a trade agreement. Thus national co-ordination of effort to allay labor disputes is ensured and local bodies are organized for the purpose of adjustment. If adjustment is impeded, there is an assurance of such inquiry and publicity as will bring the force of an enlightened public opinion to bear upon the disputants. The meeting of the contending parties with other men versed in the questions at issue is

bound to assist a settlement; a refusal to submit the dispute to adjustment will instigate an inquiry and create prejudice against the party that is obdurate. The fact that membership on the board of inquiry is available to either party singly will tend further to weaken the position of the recalcitrant side. When both parties join, the Board at once proceeds to an adjustment, and conflict ceases by agreement until a decision is reached. The plan is national in scope, but decentralized. "It is based upon American experience and is designed to meet American conditions," says the report, which is signed by Mr. W. B. Wilson, the Secretary of Labor, as chairman, by Mr. Herbert Hoover, as vice-chairman, and by the 14 members of the Conference. It needs no great analytical insight to detect the intellectual leadership of Mr. Hoover in the findings, and even in the phraseology of the report; through it all runs the same clear common sense, the recognition of the basic principle of American democracy (an equality of opportunity), and the human sympathy that has made the name of Hoover synonymous with highly organized beneficence.

Public Office and Private Practice—I

An old controversy has been revived lately, namely, should university professors engage in private practice and should Government bureaus conduct experiments and make reports for companies or individuals? For example, the College of Agriculture in the University of California maintains a bureau for scientific research that includes an organization for giving all kinds of professional advice and for affording direct assistance to farmers, not simply in a general way but as regards their specific problems on their own pieces of land. Furthermore, the College maintains an Extension division that gives instruction to farmers on all sorts of definite practical matters much of which is in the nature of personal professional advice. This condition of affairs has prevented the development of a body of agricultural experts in California and has killed the professional practice of the graduates from the College. Suggestions have been made for the organization of an engineering experiment station at the University, to be created primarily by aid of Federal funds, but to be housed by the University. Such a station would, like the agricultural, become an office for giving professional advice gratuitously, thereby competing with consultants now in practice, including the University's own graduates. In normal times many samples of minerals and rocks are sent to the University for assay or analysis, but the senders are informed, both by the Mining department and by the Geology department, that commercial work is not done at the University, and they are referred to established assayers of San Francisco and elsewhere. In the Geology department it has become the custom recently to make qualitative determinations on minerals and general 'field' determinations on specimens of rock, and to advise in a general way concerning the probable demand or market for the materials submitted for examination. There is, however, no regular

office established for this purpose; the time used on such work has been taken from the spare time of the professor making the determination, which is made largely as a matter of courtesy and good-will, without charge. It happens frequently that a prospector finds something new to him; he wishes to get an idea of what it is and whether it may be of value; he cannot send it to the assayer and say, "Test this for gold and platinum", or some other particular metal, because he has no idea of what it may contain or whether it has any commercial value. If such material requires assay or analysis, he is advised to that effect and referred to a reputable assayer in the City. The amount of such work varies considerably from time to time; occasionally it becomes somewhat of a nuisance or burden to the individual to whom the specimens are sent or submitted in person, but it appears to be rather difficult for a member of the University faculty to take a positive stand that he will express no opinion to a visitor or to one who writes concerning a matter on which he is supposed to be more or less of an expert. Sometimes the amount of labor entailed is so great that nobody is willing to undertake it. Thus it is evident that the action to be taken by the professor or instructor resolves itself into a question of personal attitude, as the University has no rules for his guidance, and it is nobody's definite duty to attend to such matters, although the administration, on receiving letters of inquiry, usually refers them to individual members of the faculty for reply. We give these facts in detail because the customs established at our State University are probably similar to those obtaining in like institutions in other States. The same problem has arisen in connection with the U. S. Bureau of Mines. In a recent case that has excited criticism, an experiment station in Oregon made a detailed investigation into the metallurgical treatment of a low-grade quicksilver ore and published a report. It was claimed that this investigation should have been left to a private ore-testing firm and that it should not have been done by a Government bureau, more particularly as the results were useful only to the one mining company in Oregon that produced an ore of this particular character. In reply, it was stated that the investigation was useful to other mining companies, in California, for example, and that the results were published for public use, not for private assistance. It is the custom of the Bureau of Mines to publish its report on any such investigations promptly for the benefit of all those whom it may assist; moreover, the Bureau aims to select such subjects for investigation as are of general interest to those engaged in mining, and such as are unlikely to be referred to private practitioners. It seems to us, from what we know, that the U. S. Bureau of Mines is careful not to compete with consulting metallurgists, although occasionally its zeal for useful service may cause it to run counter to the ideas of those inclined to be hypercritical. The U. S. Geological Survey requires its officers to take an oath not to engage in private practice within the United States and not to divulge the information that they obtain in the course of their study

of geological conditions in particular mines, except in the printed reports duly published for the benefit of the industry as a whole. Occasionally a member of the Survey resigns and later becomes retained professionally by a mining company; it is then his primary duty to respect the spirit of his obligations as a former officer of the Survey and be keenly on his guard not to misuse the information that he obtained while under the restrictions of secrecy. Some years ago there arose a scandal at Butte owing to the laxity of an ex-Government geologist, but, in the main, the honor of the Survey has been respected, so that it is very rarely indeed that it has been possible to make any just complaint on this score. However, although the geologists of the Survey are not permitted to engage in private practice in their own country, they are free to do so abroad. They have availed themselves of the opportunity to make reports on mines just over the border, in Mexico and Canada, and farther afield in other regions. In doing so they have used their prestige as Government experts to compete with independent practitioners, and, what is worse, they have diminished the prestige of the U. S. Geological Survey, because their reports have not been worth the fees paid for them. The plain truth is that the scientific study of a geologist, unless supplemented by previous practical experience in mining operations, is not worth much as a means of valuing a mine. The opinions of even such men as Clarence King and S. F. Emmons concerning the prospects of a mining enterprise had an academic interest only; they failed in making a reliable commercial appraisal. We recall how one of our most distinguished of living geologists was engaged to report upon a group of alluvial mines in Australia and how he described the geologic history of the deposits with skill and insight, but he was unable to estimate the amount of gold or the quantity of water in the gravel, because he was without practical experience either in the sampling or the working of such mines, so that his report was entirely too optimistic, failing altogether to forecast the disaster that overtook the enterprise at an early date, owing to insufficient gold and excessive water. We venture to say that the true scientist usually lacks the commercial sense; he is utterly unfitted to appraise mines, and when he engages to do so, he is doing something *supra crepidam*; in short, it would be right and proper, and for the good of all concerned, if the U. S. Geological Survey were to extend the scope of its regulations and place an embargo upon mine-reporting by its members not only at home but abroad. This should not interfere with the 'lending' of its best men for important work in behalf of other governments, for example, to perform such work as would enlarge the knowledge of our Federal geologists and contribute to the growth of the science itself, but even then it should be stipulated that the results would be published in English in this country; and of the fee, which should be large, one-half might be set aside for a fund to assist super-annuated members of the Survey. We shall discuss other phases of this subject, with particular reference to professors, in our next issue.

DISCUSSION

Silver

The Editor:

Sir—There has been a great deal written about gold during the past year, while silver has been comparatively neglected. I believe that if an authoritative article on the status of silver was published in the 'Mining and Scientific Press' it would be heartily welcomed.

I have heard many reasons advanced to support the belief that the price for silver will be maintained at a high average for many years to come, but have heard very few opinions that hold to the contrary. Let me enumerate some of the former:

India and China must take greatly increased quantities, because the standard of living in those countries has been advanced greatly, perhaps doubled, and therefore approximately twice as much silver will be needed by them in the future as in the past. The former Russian Empire and the new states in Europe, as well as some of the old ones, are quite 'fed up' with paper currency and will demand metallic money in the future. Mexico, as you know, has passed through such an experience, and, it is argued, the same thing will happen in the countries mentioned. The United States and the principal European countries will require a greater amount of silver for circulation purposes than formerly, in order to meet the demands of higher prices and a greater volume of business than before the War. The arts employing silver will require an increasing amount annually.

The prospect for a decline in gold production supports the belief that eventually silver will have to be remonetized throughout the world.

It would be most interesting and instructive to see an article showing the annual demands of India and China and the amounts absorbed each year by these countries; the world's silver production, showing the amount produced from mines operated primarily for the production of silver as distinguished from other mines in which silver is a secondary consideration; the annual requirements of the arts; the annual requirements of the world's coinage; the possibilities of greatly increased production should the price remain at a high level.

We all remember, about ten years ago, when several new 'porphyry coppers' were about to commence production on a grand scale, how many of the authoritative voices in the copper world predicted an overproduction and consequent drop in price; and how, even before the War, the increased production was easily absorbed and the warnings of the prophets were proved to have been unnecessary.

Is there much encouragement for hoping, in the case of silver, so long the "weak sister" among the metals, that a high level of prices is to be expected indefinitely, regardless of increases in production?

Culiacan, Mexico, December 1. E. P. CRAWFORD.

[By this time Mr. Crawford will have read the editorial on the status of silver in our issue of December 20. We have discussed the subject a number of times during the last six months, for, of course, it concerns a great many of our readers. —EDITOR.]

Gold and Silver as Money

The Editor:

Sir—Responding solely to the rule of supply and demand, silver has acquired a position in the commercial world which brings it on a parity with gold; in other words, 'bi-metallism' promises to be re-established regardless of the wishes of Wall Street and the mono-metallist. The rapid advance in silver quotations has startled the financial world and the fact that a silver dollar is worth more in bullion than it is in coin will result in the final withdrawal of silver from circulation. It will be as scarce in the transactions of business as gold is already.

Disturbance of exchange-rates on international money transactions is a natural result and direct outcome of the War; principally this is due to the enormous credits. The business world is unable to readjust its operations on the basis of the present gold standard.

The Government must resort to some expedient of re-coinage, and to do this we must remove the old standards of value which were established by an act of the British parliament in the year 1802, and adopted by the United States government in the year 1820; otherwise, in order to maintain the old standard, we must increase taxation to practically double the present levy.

The fundamental object of taxation is not to impose a burden or a penalty on the taxpayer; rather the opposite; to secure funds by means of which the Government may be enabled to extend to the taxpayer those benefits which he could not so well, if at all, secure for himself. Consequently, any program of taxation should be administered with the utmost sympathy and consideration and with the least possible disturbance of the taxpayer's normal activities. Already taxes have been levied until these burdens cannot be carried by the common people, and to tax industry further means to curtail

the output, lessen the production, and thereby increase the cost of living.

Nations as well as individuals must pay their debts. Today the United States of America is the only solvent concern in the world; and it is carrying a bonded indebtedness of practically thirty billion dollars or a principal sum of \$275 for each person in the United States. The interest levied pro rata would be \$13.75 a year.

The first duty the Government owes its people is to begin paying its debts and get back to doing business as soon as possible on a hard-cash basis, which is a sure cure for the economic ills of the nation. But how can this be brought about? First, Congress should adopt a measure for protecting the Treasury reserves and reducing taxation. This can be done by adopting a bi-metallic monetary system. Call in all metallic specie and re-issue gold and silver coins in one-half the present size. With the surplus from re-coining, retire a portion of the present bond issues. Then adopt a standard for gold at \$41.34 per ounce and a value for silver of \$2.50 per ounce. Such an act of the Government will relieve the burdens of taxation and will greatly stimulate the mining industry; it will pour more wealth into the coffers of the Treasury; labor will be employed at a wage that will do away with strikes, and the opportunity will be offered to every person in the United States to receive employment. The reducing of the size of the American dollar will give a dollar a purchasing power equal to its value and will enable the United States as a nation to expand its industry and commerce and in this manner we will have solved the question of the High Cost of Living and reduce taxation.

Omaha, December 15.

ROY M. HARROP.

[Our correspondent suggests a variety of measures with which we disagree entirely, but it is our policy to give space to expressions of opinions opposite to our own.—EDITOR.]

The Crowe Process

The Editor:

Sir—Referring to the various discussions on this subject, the contention that the application of the process by Mr. Crowe was not original does not appear to be well founded nor well supported. That the principle was understood and frequently mentioned in literature on the subject cannot be questioned, but that anyone fully appreciated its importance or made any deliberate attempt to apply the principle remains to be proved. All claims that have come under my observation rest on accidental or incidental application in connection with vacuum filtration. That any appreciable benefits were derived by incidental application of the vacuum in filtration is questionable. I think the only claims worthy of consideration are those by Philip Argall, and these are supported more by his reputation than by his statements, which it is the purpose of this communication to prove.

It is my understanding that the material question is whether or not anyone anticipated the Crowe process by deliberately subjecting a pregnant solution to a vacuum for the purpose of improving precipitation by the re-

moval of oxygen. I do not question that Mr. Argall is sincere in his belief that he either accidentally or intentionally anticipated the Crowe process. However, he does not make any definite statements that it was intentional, but he has presented his data in such a way that the natural inference is that the application was intentional. This presents a rather delicate situation, and I am forced to say that if the application was intentional the methods were decidedly crude for one of Mr. Argall's attainments. The purpose of this letter is to prevent the uninitiated from 'kidding' himself into the belief that the benefits of the Crowe process are obtainable by the arrangement described by Mr. Argall.

Permit me to digress for a moment to criticize Mr. Argall's terminology. I will show later that the point I make has some bearing on the question. I object to the use of 'gas' as a substitute for 'air'. Strictly speaking, it is correct, but it is not generally used, and general usage is, I take it, the measure of accuracy. The use of 'gas' to distinguish air in solution might be permissible, but Mr. Argall does not make this distinction. To quote, page 393, second column, line 14: "The evolution of gas, however, proved so vigorous that foam occasionally passed over into the air-pump." This statement is decidedly misleading. The natural inference is that the evolution of gas was a measure of the efficiency of the vacuum in separating dissolved air from solution. On the contrary, it was a measure of the inefficiency of the filter. Water absorbs about 2½% by volume of air at 0° and sea-level. This varies inversely as to temperature, altitude, and amount of salts in solution. The decrease is compensated by expansion at higher altitudes, and if volume is considered, which is quite proper, the proportion might be slightly greater than the amount stated. In any event, it is insignificant. The amount of air passing through a vacuum system of a leaf-filter is roughly speaking from 10 to 100 times the amount necessary to saturate the solution handled. Hence my objection to the general terms, 'gas', 'de-gasser', and the paragraph previously quoted. I would like to ask Mr. Argall why he did not "de-gas" the solution from the leaching-vats if, as is intimated, he at that time realized the advantage of doing so.

I cannot see what bearing the amount of zinc used per ton of ore has on the question. This could be of only comparative value under any circumstances. The real measure of efficiency in precipitation is the ratio between the zinc and the metal precipitated. The evidence offered by Mr. Argall could be duplicated indefinitely, as the arrangement described was the usual one and dates from about the time of the introduction of the vacuum-filter. I cannot, however, see that it has any relation to the Crowe process. In slime-filtration the filtrate is usually turbid, especially with a leaf-filter, and clarification is a necessity.

Mr. Argall states that the solution was pumped from the separator to clarifiers, presumably sand-filters that served also as storage. The latter is not material.

E. M. Hamilton called our attention many years ago to the fact that cyanide solution containing a considerable excess of sodium sulphide was completely oxidized by

simply decanting from one tank to another. I quote this to illustrate the avidity with which cyanide solution absorbs air; and this is the point I wish to emphasize. The transfer of solution to an open tank after 'degassing' will result in neutralizing the effect almost instantly, and I hold that the essential feature of the Crowe process is contact with the precipitant after degassing without exposure to air. If anyone can establish the fact of having done this previous to Mr. Crowe he can fairly claim to have anticipated the invention.

El Paso, December 16,

JAMES S. COLBATH.

Fine Grinding in Ball-Mills

The Editor:

Sir—In looking over my article in your issue of January 3, I notice that graphs, Fig. 1 and Fig. 2, showing the sizing of feed to the mill and discharge from the mill

Fig. 1

Fig. 2

in plotted curves after five and ten minute grinding-periods were omitted inadvertently. I take this opportunity therefore to make the correction. The graphs are referred to on bottom of page 17 and top of page 18 of your last issue.

HENRY HANSON.

San Francisco, December 31.

Mine Surveying

The Editor:

Sir—There are certain statements in the third installment of Mr. Waterman's series on 'Mine Surveying', particularly regarding the use of the 500-ft. tape for slope measurements, that I should be inclined to question. I have never done any mine surveying but have used both a 300 ft. and a 500 ft. tape extensively for surface work, and also in running railroad tunnels, the latter for setting points in the heading before the bench below had been taken out.

My experience indicates that to get a really accurate reading by simply measuring to a point on a plumb-line is impossible, even with a 300-ft. tape, much more so with a 500-ft. tape. In fact, even with a 100 ft. tape, it takes a careful and experienced head chain-man to give the tape the required tension to take up the sag, prevent the tape from disturbing the plumb-line, and read the tape, all at the same time. With a 300 or a 500-ft. tape errors of 0.1 ft. or more cannot be prevented.

The method that I have found to give the maximum accuracy, for reasonable expense in time and money, is to set a stake on line, taking special precautions to make it solid, centre it with a tack, and take the measurement to the tack. Where a stake cannot be driven because of rock, use a 'gad' or something similar, and scratch a temporary point on the top. Four men are needed for a really accurate measurement, provided the distance is much greater than 100 ft., one at each end to pull on the tape, and one at each end to read it. If extreme accuracy is desired, a spring-balance and a thermometer should be used, and the observed length corrected for tension and temperature. Except for special cases, I do not believe that the slight saving in time for the 500-ft. as compared with the 300-ft. tape compensates for the greater convenience of the shorter tape. There is, however, no question that the use of slope-measurements corrected for the vertical angle gives greater accuracy and speed for both surface and underground work than where the method of 'breaking chain' is used.

San Francisco, December 19,

A. T. PARSONS.

The Burma Mine

The Editor:

Sir—In your issue of November 29, under the heading of 'The Burma Mine', the following statement appears: "Mr. R. G. Hall formerly in Missouri is resident manager. He succeeded Mr. C. H. MacNutt, who resigned in 1916 and served with the engineer corps of the Canadian army in France."

Apparently you are not aware of the fact that Mr. Thomas E. Mitchell succeeded Mr. MacNutt as resident manager in 1916 and continued in that capacity till August 1918. Mr. Mitchell as mine manager, and afterward as resident manager, not only developed the mine to such an extent as to expose several million tons of ore, but also conducted this work so efficiently that in the future the Burma Mines Ltd. will be noted for its low

cost of mining operations. A resident manager, too, owing to his energetic control of operations, he was responsible for the great progress in metallurgical and engineering operations which marks this period in the history of the company.

W. SHELLSHEAR.

San Francisco, December 2.

[Yes, we were aware of Mr. Mitchell's management, but overlooked it inadvertently. We are glad to publish this correction, and with it the tribute to his good work by one who is well qualified to pass judgment.—EDITOR.]

Panama Museum

The Editor:

Sir—I have just received a letter from the Director of the Colegio de La Salle, Plaza De San Francisco, Panama City, requesting the co-operation of the Bureau in securing additional material for the mineral collection of the museum, on the ground that a great many people from almost every nation in the world pass through Panama and visit the museum, and that an adequate exhibit of American material there should be of benefit in contributing to a greater knowledge of American materials and the extension of trade.

On this ground the Director asked me to request the principal mining firms of the United States to send the museum samples of their minerals and products. As the columns of your journal are the most effective way of transmitting this request, I am passing it on to you for such action as you may deem desirable.

Simplified Spelling

The Editor:

Sir—I thank you for the opportunity to reply to your editorial note of December 27, though I wish you had allowed more space. In the 1917 election 765 ballots, a majority of 336, were cast in favor of the adoption of the 12 words recommended by National Education Association. This majority was nullified by the unusual method of counting blank ballots as negative votes. It, therefore, seems very probable that if the overwhelming vote you demand is forthcoming that other reformed spellings will be adopted, *tho* and *thru*, for example. I welcome the publicity now being given to the spelling-vote, for if the arguments are carefully studied, I feel sure, gain will result to spelling reform. The Institute now uses so many reformed spellings (catalog, gram, program, sulfur, sulfid, and others) that this anguished plea for protection against the admission of a few more short spellings seems childish. The title of page xx of the December bulletin, "Simplified Spelling Foisted Upon Us", seems an improper designation to apply to the attempt to ascertain the wishes of members by a procedure explicitly set forth in the constitution of the Institute. The paragraphs you

mention, as an example of the horror of simplified spelling, were not written by me and I first saw them in the Bulletin. I am using reformed spellings in my notices, but these spellings have been authorized by a vote of the executive committee of the San Francisco section. While I deeply regret that any of my actions should have irritated you, yet I cannot help feeling that the underlying source of your irritation is a subconscious feeling that there is more justice on the side of the spelling reformers than you consciously realize. On page 912 you quote that 25% of the drafted men could not read or write. Educators attribute much of this illiteracy to our difficult spelling. The Chinese government, in November 1918, authorized a system of phonetic spelling that enables the illiterate Chinese to learn to read in a month; so important is this considered by the governor of Shansi that he has ordered every person in his province to learn to read instantly under severe penalties. Can we not follow, even if far behind, the progressive Chinaman? The argument that it is not the business of the Institute to benefit the coming generations seems especially weak, for we shall benefit most by adopting an additional measure of simplified spelling and the benefit to the children will be incidental.

W. H. SHOCKLEY.

Written amid the melting snows. Truckee, December 29, 1919.

[Whether "amide" is simplified spelling, we do not know. Mr. Shockley was told that he could have as much space to reply as the Editor took for his paragraph. Of course, we feared an inundation of propaganda for 'simp' spelling. Mr. Shockley is not quite correct when he says that his use of his way of spelling was authorized by the executive committee of the local section; the fact is, he used it before such authorization was given. We hope earnestly that members of the Institute will not fail to vote on the question, taking care not to be confused by the obscure way in which the issue is stated in the official circular. In the 1917 vote, only 1194 members, of 6000, voted; unless members pay attention to the matter, we may be victimized by Mr. Shockley's persistent propaganda.—EDITOR.]

QUICKSILVER, although not a precious metal nor like iron, copper, and zinc one of the great basic materials of industry, nevertheless has the unique position of being the only metal that is liquid at ordinary temperatures and its varied and special applications in science and the arts give it peculiar interest. A report of the U. S. Geological Survey, prepared by F. L. Ransome, not only gives the domestic production of quicksilver as a whole and by States for the year, but presents also the latest obtainable figures for the world's production and contains information on the quantity and character of ore treated, methods of reduction, prices, imports and exports, and uses of quicksilver. The report also contains notes on the operations at individual mines and a table wherein are listed most of the quicksilver mines of the United States with notes on the character of the ore deposits, reduction equipment, and total output of each mine.

The Bunker Hill Enterprise - II

History of Idaho and Beginning of Mining Operations

By T. A. RICKARD

The historian Bancroft says of Idaho: "Taken altogether, it is the most grand, wonderful, romantic, and mysterious part of the domain enclosed within the federal union." I shall not quarrel with his eulogy, for it is my desire to interest the reader in that part of the United States in which is the subject of these articles, the Bunker Hill mine. Besides the locality of this celebrated mine, I have some acquaintance with other parts of Idaho, and, if more sparing in adjectives than the historian of the Pacific Coast, I can testify that Idaho is a beautiful and interesting region. The word 'Idaho' is generally supposed to mean 'Gem of the Mountain', and it may well be agreed that the State is a jewel in the crown of Uncle Sam; but there is another and more probable derivation. I am told that 'Idaho' is an Indian word used by the Nez Percés to describe the phenomenon observed in the early morning when the nearly horizontal rays of the rising sun touch the mountain-tops while the valleys are still shrouded in darkness. It is what we would call a 'sun-burst'.

We have traced the early history of this north-western region up to the point when it became a part of the United States and was organized as the Territory of Oregon. When the whole of Oregon became a State, in 1853, it retained the southern portion of the present State of Idaho, but lost the northern portion, which became included in the Territory of Washington. This remained within Washington until 1863, when the Territory of Idaho was organized, with William H. Wallace as Governor; this included the present State of Montana until 1864 and a part of Wyoming until 1868, when the area of the Territory of Idaho was reduced to that of the present State. In 1890 Idaho was admitted into the Union, and the first Governor was George L. Shoup.

That part of the United States now comprised within the State of Idaho was first explored by white men when the Lewis and Clark expedition crossed it in 1805. They traced the Snake river to its junction with the Columbia, as we have seen, and they made Fort Lemhi a rendezvous for the two divisions of their party. They camped among the Nez Percés on the south fork of the Clearwater river, where, it is said, they found traces of other white men. Indeed, it is noteworthy that the explorers famous in the history of the West have usually found other white men ahead of them—French trappers, British fur-hunters, or American prospectors—who had made friends with the Indians and married among them, becoming 'squaw men', and thereby being admitted to the aboriginal knowledge of the country. Such was Chaboneau, the French-Can-

dian trapper who married the famous Sacagawea, a Shoshone woman, with whom he accompanied the Lewis and Clark expedition, to which both husband and wife proved of great service as guides. Another was Drewyer, the son of a Canadian and a squaw, who was particularly helpful in killing game for food in January 1805 when the same expedition was extremely short of provisions.

The rivalries of the fur companies caused Idaho to be explored again at a later day. In 1810 Fort Henry, on the Snake river, was established by the Missouri Fur Company, which had done so much to impede Astor's representative, Hunt, in his journey to the coast. In 1811 a party of the Pacific Fur Company, controlled by Astor, descended the Snake to its junction with the Columbia. Then came missionaries, both Catholic and Protestant, among the Indians. These traveled along the trails that the trappers and packers had established across the Bitter Root range, which separates Idaho from Montana and the Missouri valley. In October 1841 Father DeSmet, a Jesuit priest, visited the western slope of the Bitter Root mountains, on his way to the coast. He descended into the valley of the Coeur d'Alene river and ministered to the Indians of that name, a name they owed to a tricky trader, whom, when he tried to get the best of them, they called *coeur d'alene*, or heart of an awl. The traders, for lack of a better name, thenceforth spoke of these Indians as the Coeur d'Alenes. They were a docile tribe and begged DeSmet to establish a mission among them. In the following year, 1842, he appeared again and in the autumn he founded the mission, for which a church was erected in the basin of the St. Joseph, a stream tributary to the Coeur d'Alene river. Owing to a flood, the church was removed in 1846 to its present site, 12 miles below Kellogg. There Father Ravalli labored for seven years, and there the signs of his artistic handiwork are still to be seen. The old church was built without a nail; instead a hole was bored and a wooden pin was driven through. The Mission became a landmark on the trail across the Bitter Root mountains from the Missouri to the Columbia valley. Father Ravalli exercised a wide influence, promoting peace among the red men and protecting the lives of the white men. The light in the window of the Mission was a beacon to many of the packers and prospectors that came down the trail weary from battling with the snow in the mountains. From the Jesuit fathers they always received a cheery greeting and found protection from the storm. It was the trade with these Indians that led to the discovery of the mineral wealth of the region.

In the spring of 1849 the gold excitement in California attracted many of the pioneer settlers from the North-West. Ten years later gold was discovered on the Similkameen, in British territory, just over the northern boundary of Washington, and in 1860 the placers of the Cariboo, at the head of the Fraser river, stimulated prospecting in this part of the world. Through participation in the working of these discoveries, north and south of them, the people of the North-West obtained some knowledge of the technique of mining and were prepared to find and to exploit the mineral riches within their own borders.

To E. D. Pierce belongs the honor of being the pioneer of mining in Idaho. He was a trader among the Indians and through them he had long known that the country east of the great bend of the Snake river was gold-bearing, but he did not dare to undertake prospecting operations for fear of arousing their enmity. He had been in California and knew something about placer mining. In 1858 Pierce re-visited the Nez Percé country, but found no opportunity to search for gold until after the ratification of the Nez Percé treaty and the general cessation of hostilities between the Indians and the white settlers in 1860. Early in that year he was enabled to verify his belief that there was gold in the gravel of the Clearwater, a branch of the Snake, and he so reported in April at Walla Walla, which was then the nearest distributing point. Pierce did not return at once to the Clearwater, on account of opposition from both the Indian and the military departments of the Government. These dreaded a renewal of trouble with the Nez Percés and Spokanes in the event of a mob of prospectors over-running their reservations.¹ In August, however, Pierce was enabled to set out from Walla Walla for the purpose of making a conclusive examination. He appears to have been a careful and sagacious man, unwilling to commit himself to an opinion until sufficient evidence was available. He ascertained that the diggings were dry and yielded 8 to 15 cents to the pan. Having satisfied himself that profitable mining was feasible, he tried to organize a large company to return with him and remain on the ground during the winter, but the fear of attack by the Indians was a deterrent to adventure, so that only 33 men were willing to accompany him. Pierce himself, although convinced that the gravel on the Clearwater was fairly rich, was quite free in exposing the disadvantages of the undertaking and did not hesitate to declare his belief that these placers were but the fringe of still richer ground. By the time 300 men had set to work in the district, which was named Oro Fino, a treaty was negotiated with the Indians. A month later the number of diggers had increased to a thousand. This was in the spring of 1861.

When the rush began from Portland and Walla Walla to the mines, a steamer went up the Snake river to the mouth of the Clearwater and up that stream to within 40 miles of Pierce City. In the early summer of 1861, the navigation company joined with the miners in selecting a site for a town at the junction of the Clearwater

and the Snake. A suitable site was found between the two rivers and it was called Lewistown, in compliment to Meriwether Lewis, of the Lewis and Clark expedition, who had discovered these rivers and had been entertained by the father of the chief of the Nez Percés almost at the very spot where Americans were now digging for gold.

By July 5000 men had scattered over the surrounding region and prospecting had been extended to the south fork of the Clearwater, where a town called Elk City was established with a population of 2000. This was 120 miles south of Oro Fino.² In July a party went still farther south to the Salmon river and in September made a discovery of gold that created such excitement as almost to empty the older mining camps. Bancroft states³ that "John Munroe purchased a claim [on the Salmon] for \$1800 and from two pans of the dirt took four ounces of gold. In two weeks he had taken out 45 pounds of dust."

Nathan Smith, a Californian pioneer, discovered gold at Florence in the following winter, 1861-62, and in 1869 the same prospector was responsible for starting mining at Oro Grande. In 1862 there was a large immigration from the Eastern States, owing to the Civil War and the fame of the Salmon River diggings. By 1863 there were four county organizations and ten mining towns, containing in all 20,000 inhabitants, most of whom were pioneers from the Pacific Coast and the Western States—a population of energetic and resourceful men. This industrial development caused the organization of the Territory of Idaho in 1863; it included all that portion of Washington lying east of Oregon and the 117th meridian of west longitude.

Shoshone county, in a remnant of which is the Bunker Hill mine, was the first portion of Idaho to be mined and settled; it was in the southern part of the county that Captain Pierce made the first discoveries. Bancroft states: "The county of Shoshone was set off from Walla Walla county by the legislature of Washington as early as January 29, 1858, comprising all the country north of the Snake river lying east of the Rocky Mountains, with the county seat 'on the land claim of Angus McDonald'." He had been the Hudson's Bay company's agent at Colville. The county was divided by legislative enactment in 1860-61 and in 1861-62 as the requirements of the shifting population demanded. Bancroft reverts to the nomadic character of the early miners and describes this characteristic in felicitous phrase: "The miners of Idaho were like quicksilver. A mass of them dropped in any locality, broke up into individual globules, and ran off after any atom of gold in their vicinity. They stayed nowhere longer than the gold attracted them."⁴

In 1863 the gold-quartz veins of the Boise basin and in 1865 the Poorman vein on War Eagle mountain, in Owyhee county, were discovered, each of these events inciting a mining stampede.

Although the discoveries of gold-bearing gravel on the

¹Pierce City was the first camp. It is at the mouth of Canal gulch, on Oro Fino creek.

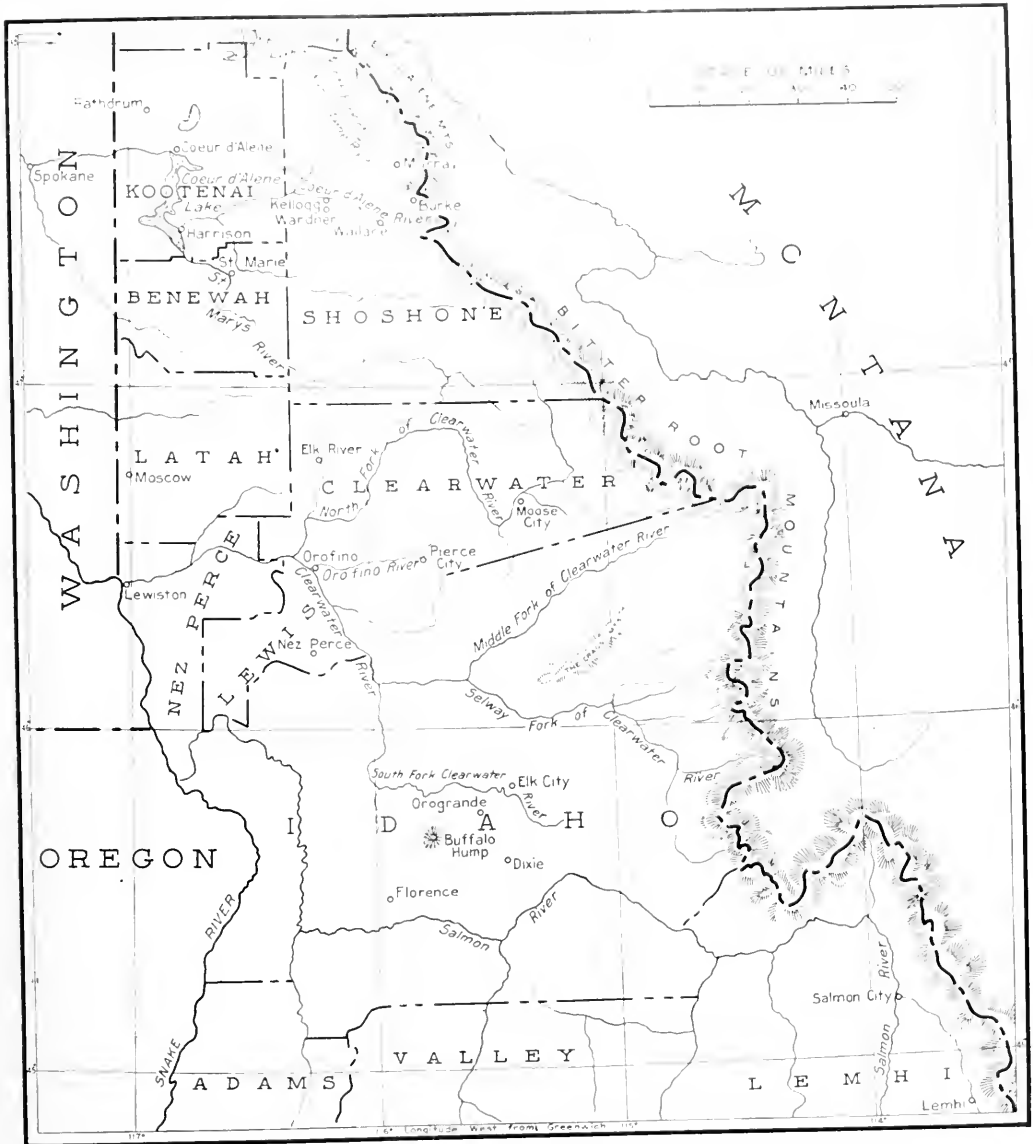

²Op. cit., p. 247.

³Op. cit., p. 427.

⁴The Works of Hubert Howe Bancroft, Vol. XXXI.

streams tributary to the Clearwater marked the beginning of successful mining in central Idaho, these diggings did not last long and their population soon drifted southward to the Salmon River and Boise districts.

These diggings proved disappointing, but six years later fresh discoveries gave new life to the district and led to the founding of Moose City, which continued fairly prosperous until the early 'Seventies. The mention of this

MAP OF NORTHERN IDAHO. THE BUNKER HILL MINE IS AT WARDNER AND THE MILLS AT KELLOGG

When the placers of Pierce City, Oro Fino, and Elk City became exhausted, they passed largely into the patient hands of the Chinese. In 1862 there was a rush to Moose creek, at the headwaters of the north fork of the Clearwater and 40 miles north-east of Pierce City.

locality is essential to my story because it indicates the northward extension of mining exploration, bringing prospectors nearer the Coeur d'Alene, the northernmost portion of Shoshone county, which by this time had become depopulated and impecunious. In 1881 the assessed

valuation in the county was only \$38,981. The 'Lewis-town Teller' of July 21, 1881, said: "Our Pierce City [which was then the county seat, it must be remembered] correspondent announces the partial disorganization of Shoshone, leaving the people of that county without any executive officers. For some time past offices in that county have been compelled to go begging for men to fill them, and when once filled several substitutions have been made after periods of interregnum. The whole number of white residents in the county seldom exceeds 75 persons, and is more often less than that. . . . The increase, when there has been any, has been principally among the Chinese, who have gone there for mining purposes and bought the greater portion of the ground that had been worked by the whites."

Fortunately the county organization was maintained, even though it was precarious. Better days, however, were in store for Shoshone. For many years the existence of gold in the Coeur d'Alene had been rumored. It is stated that as early as 1853 gold was discovered in the Coeur d'Alene by Donelson, of the Stevens expedition, but the hostility of the Indians kept prospectors out of the country. In 1858, when Lieutenant John Mullan surveyed the military road across the Bitter Root mountains, the members of his expedition, most of whom had mined in California, noticed outcrops of likely-looking quartz and some of them actually found gold, as is recorded in a letter that Mullan wrote, from Washington in 1884, to the editor of the 'Eagle', a paper published at Eagle City, of which mention will be made later. Mullan, in that letter, told how one of his hunters, named Moise, a French-Canadian, had come into camp one day with "a handful of coarse gold which he said he had found on the headwaters of the north fork of the Coeur d'Alene". His statement was discredited, it being assumed that "he had traded for this gold with some parties passing up and down the Fraser River mines", as Mullan says. This was in 1858-59. Other finds were made by Mullan's men at intervals along the trail that he surveyed across this region, but he did nothing to encourage interest in them because he feared to lose his men and thereby endanger the completion of the task he had in hand, which was, as he says "to open a base line from the plains of the Spokane on the west to the plains of the Missouri on the east, from which other lines could be subsequently opened, and by means of which the correct geography of the country could be delineated". He aimed to ascertain the most practicable route for a wagon-road that could eventually become the line of a railroad; and he succeeded, for the Mullan trail was followed later by the Northern Pacific railway.

The white men that first penetrated into this region found a trail leading past the Old Mission. Over this trail the Indians used to cross the Bitter Root range and when the time came to build a wagon-road, the surveyor, Lieutenant Mullan, found no better route; when the Northern Pacific sought an entrance into the Coeur d'Alene, it, in turn, could find nothing more suitable than the Mullan road, and so the old trail became the line of a

railroad.* From Wallace to the Mission the railroad followed the mossy feet, and from there across the lake the steamers followed in the vanished wake of the Indian canoe. The old narrow-gauge line was built in 1887 by the late D. C. Corbin, the famous railroad-builder of the North-West; it extended from Burke to the Mission landing, and in 1896 was replaced by the broad-gauge line of the Union Pacific which entered the Coeur d'Alene from Tekoa, Washington.

In 1873 Frank Peck and John Vollmer found gold in the course of a prospecting trip between the St. Joe and Clearwater rivers, but nothing came of it. The first successful prospector in the Coeur d'Alene was Tom Irwin, who worked a quartz vein on the Mullan road, near a place called the Miner's Cabin, in the spring of 1879. He formed an opinion that gold-bearing gravel would be found in the vicinity, but he failed to find any. In 1881 he met A. J. Pritchard, who was engaged in the lumber business, and told him what he thought of the prospects of placer mining in the upper reaches of the Coeur d'Alene river. This was in 1881. Soon afterward Irwin went to Colorado, but Pritchard had become interested. To him belongs the credit for disclosing the riches of the region. In 1882 he found gold on several of the creeks tributary to the north fork of the Coeur d'Alene river. One of his first finds was on Eagle creek, but his most important discovery was on the creek that is now known by his name, at a spot near the site of the present town of Murray. In March 1883 he located four claims, one of which was in the name of his son, and the other three in the names of personal friends, he himself retaining a half-interest in each claim. Besides this discovery group, he located a number of other claims for various friends by power of attorney. Pritchard belonged to an organization called the Liberal League and he was anxious that his friends in the League should have the first chance to share the benefits of his discovery, so he wrote a letter, reproduced by the 'Spokane Review' in 1888, in which he invited them to come to Idaho and "secure the lion's share" of the mineral wealth he had uncovered. His letter is dated January 7, 1883, and is written from 'Evolution', which was the name of his camp on the Mullan road. It is so interesting that I shall quote the principal portion of it:

"I have made a discovery of a gold-bearing country that will give employment to at least 15,000 to 20,000 men. There are two streams that I have prospected well; one is 16 to 25 miles long, as near as I can judge; the other 12 to 16 miles and an average width of 60 to 70 rods; have found gold on three other streams of near the same size, but have not tested them enough to know how they will pay. The two streams I speak of will pay their whole length and probably the most of their tributaries, with an abundance of good timber and water. Bedrock from 5 to 12 ft. Gold coarse and of good quality. There are two good and natural town-sites where there will be built cities representing thousands in

*'Following Old Trails', by Arthur L. Stone, p. 162.

less than two years, and the country is traversed with hundreds of mineral-bearing lodes of quartz. And now for good reasons which I have not time to explain I would like to see as much of this go into the hands of the Liberals as possible, and also see them build a city where they can have their own laws and enough of this vast mining region to support it, which they can do if they

that have to buy horses would be to stop at Spokane Falls, Washington Territory, which is 30 miles from the post, and perhaps they might do better in provisions and groceries, tools, etc. Now, if there are many that conclude to come, they might leave the impression along the road that they were going to Montana and give as many Liberals as possible a chance to get in before they get up an excitement."

Prichard's letters caused a stampede from Montana and Colorado to the gold belt of the Coeur d'Alene in the spring and summer of 1883. His Liberal friends were not discreet, but allowed the news to leak out, so that it reached the Black Hills district, in South Dakota, and induced a crowd of miners to migrate to Idaho. When these, and others from other parts of the country, arrived, they found that Prichard had located all the

NORTH FORK OF THE COEUR D'ALENE RIVER

will go at it cool and work together. I have spent four years by myself looking and working it up. I first discovered and located a lode in the Mullan road, and not having much means to open it up, I spent all of my spare time looking for placers, not anticipating finding extensive mines, only something to help me open my lode, but I have found a richer and bigger section than I supposed lay undiscovered in the Rocky range, and now if you will convey the purport of what I have given you to as many Leaguers as you can on this coast, and request them to get together and keep this information to themselves, they can secure the 'lion's share'. I am in the mountains, fifty miles from a post-office, and can do but little in winter, for the snow gets from three to four feet deep here. I will give directions how to get there and what is needed. My location I call Evolution, as that is the name of my lode. It is on the old Mullan road to Montana. I am 50 miles east of Fort Coeur d'Alene and 23 miles east of the Old Mission. The Northern Pacific railroad runs within 12 miles of the post, where there is a town called Rathdrum. Parties coming will want pack-animals, as the new mines are back from my place on the road 40 miles in the mountains, with but poor pack-trails yet, as I have not had time to cut them out more than enough to get through, and they will want supplies for a month or two, as there will be no chance of getting anything after leaving the post at present. Probably the best place for those

THE OLD MISSION

best ground by power of attorney for his friends. They began at once to jump his claims. This led eventually to a long and costly series of litigations. Another cause of trouble arose from the fact that many farmers from the Palouse country and others whose principal occupation was not mining took advantage of the law to locate a claim—20 acres of placer ground—and hold it by doing the small amount of assessment work legally required, without engaging in active development, meanwhile giving their attention to their business elsewhere. The real prospectors found much of the best ground plastered with locations belonging to men who left them unworked; whereupon, of course, they jumped them. This led to litigation and sometimes violence.

Among those attracted to the district in 1883 was H. C.

Davis, of the Northern Pacific railroad, who saw an opportunity to secure patronage for his road and to encourage a settlement of the country contiguous to it. So he issued a circular, which has become famous in local history, because it induced a further rush to the district in the winter of 1883-84. It is amusing on account of its flattery, and phrasing, worthy of the prospectuses of a later day. I quote herewith:

"The claims are very rich, and are located in the gulches of the north fork of the Coeur d'Alene river, Eagle, Pritchard and Beaver creeks, streams running into the Coeur d'Alene. Rich placer deposits have already been discovered for a considerable distance on Pritchard creek and the same distance on Eagle creek, the creeks being known by the latter name from the point where they come together. Nuggets have been found which weigh \$50, \$100, \$166, and \$200. An intense excitement has sprung up in regard to the quartz deposits of this district, the immediate occasion of this being a find of a valuable quartz lode at the head of Pritchard creek. The vein has been traced on the surface for a distance of five hundred feet and the outcroppings are very prominent. The ore taken from the vein shows a great amount of free gold; in fact, it fairly glistens. The most extensive galena belt known at the present day is being developed on Beaver creek. The vein can be readily traced on the surface for five or six miles, the ore carrying from 80 to 90 ounces of silver and 35 to 40% lead. Such is a brief sketch of the Coeur d'Alene mines, which surpass in richness and volume the most fabulous quartz and placers ever discovered, even the famous deposits of Potosi being inferior to those which underlie the mountains of the Coeur d'Alenes. As the mines of the old world, some of which have been worked since the eleventh century, are still employing thousands of men, the conclusion to be drawn in regard to the Coeur d'Alenes, a region far superior in every way, is that they are inexhaustible, and although thousands may work them, there will still be room for thousands more."

The first town to be laid out was Eagle City. In March 1884 lots sold at prices ranging from \$200 to \$2000. In the 'Nugget', the local paper, of March 22, 1884, it is stated that twenty new business houses were opened in the mining district during the preceding week. In the same issue appears a warning against any Chinaman entering the camp on pain of expulsion or death, and the expulsion of the person importing any such Chinaman. Mail on letters cost 50 cents and it took as much as two weeks to make delivery from Spokane Falls. The buildings were made of logs and 'shakes'. Shoveling of the snow in front of them left a mound between them and the street. Big tents, with gaudy signs, emitted sounds of rudimentary music, the click of chips, and the clink of coin passing over a bar. At the corners stood groups of men talking mines and mining, some of them examining specimens as they were passed from hand to hand. The stores exhibited specimens of gold-bearing quartz. A pistol shot would cause a transient flutter and the saloons would momentarily disgorge

a crowd. Pack-trains arrived, weather-worn and dilapidated from hard usage. The sounds of carpentering indicated the growth of the town. An air of expectation pervaded the community. It was full of life and hope—a transitory gleam. Eagle City soon lost its eminence; other 'cities' sprang up like mushrooms in the night; among them were Carbon City on Beaver creek; and Myrtle on Trail creek. Each of these had its little day; they flared up, only to be extinguished as the chances of discovery diverted the migrating population from one scene of excitement to another. As Bancroft says, it was a "mercurial" community, that of the miners.

In April 1884, encouraged by Pritchard, a number of men went to Canyon creek and staked claims. Nine-Mile also was prospected. It is said that some of these prospectors filed claims on the very ground in which the famous silver-lead mines were developed at a later date, but they were looking only for placer gold, and, being without experience in any other kind of mining, they missed many chances.

The 'History of Northern Idaho', from which I have obtained some of my information, has much to say concerning the homicides and other acts of violence that punctuated, and punctured, the life of the pioneer settlements. It is pathetic to see so much space given to details that today possess nothing except a morbid and mortuary interest. For example, here is the record of a crime perpetrated at Murray in 1884.

"A homicide which attracted wide attention and roused the community to a high pitch of excitement was the killing of John Enright by Henry Bernard, July 2, 1884. The victim was a compositor in the office of the 'Pioneer', of which paper Bernard was editor. It appeared from the testimony at the preliminary hearing that Enright had been discharged and paid the afternoon of the homicide; that he came to the office for his blankets, but, instead of taking them and going quietly about his business, kept complaining to Bernard of the shabby treatment which he claimed had been given him. Bernard told him to go two or three times, but he still hung around the office. Finally Bernard drew a revolver and pointed it at him, telling him he must leave or get hurt. Enright received the threats in a jocular manner, and soon the fatal shot was fired."

At this time the county seat of Shoshone was Pierce City, as the reader will recall. When the northern mining districts began to assert their preponderant importance, there arose the demand for a change. The State legislature of 1884-85 passed a bill providing for the removal of the county seat temporarily from Pierce City to Murray and for a special election to be held in the county in June 1885 for the purpose of selecting a county seat. Osburn had the honor for a time. This, however, was a trivial matter compared with the finding of the silver-lead lodes in the autumn of 1885, for to them the Coeur d'Alene owes its enduring fame as a mining region and with the discovery of them begins the story of the Bunker Hill enterprise.

(To be continued)

A Contribution to the Study of Flotation—II

By H. LIVINGSTONE SULMAN

MOLECULAR CONSTITUTION OF SOLIDS AND LIQUIDS

According to the molecular theory, solids, liquids, and gases are composed of finite, physically indivisible particles or molecules, separated from each other by distances which are comparatively very small in solids, somewhat greater in liquids, and large in gases. All are in rapid motion, which increases with rise in temperature, and decreases with its fall; molecular motion, and consequently all chemical action ceases at absolute zero ($-273^{\circ}\text{C}.$). At $0^{\circ}\text{C}.$ the average velocity¹ of a molecule of hydrogen gas is computed to be 4100 miles per hour, or rather more than one mile per second. The velocities of molecules of other substances at equal temperatures are inversely proportional to the square roots of their molecular weights;

thus a molecule of silica at $0^{\circ}\text{C}.$ would travel at $\frac{4100 \times 1.2}{1.56}$ miles per hour, or about one-quarter mile per second. The average distance traveled between collisions will be small in a liquid and still smaller in a solid.

In a gas, the molecules are continually colliding with each other; being perfectly elastic, they rebound without loss of energy, and their impacts with the molecules of the walls of a containing vessel constitute the pressure exerted thereon by the gas. At atmospheric pressure the average travel between successive collisions (the gaseous 'mean free path') is about $\frac{1}{4,000,000}$ of an inch.

In liquid water, the molecules travel at an average speed of about one-third mile per second; being closely packed, their mean free path is small, probably less than the diameter of a molecule. Nevertheless, they move freely among themselves, giving rise to the mobility of the liquid as a whole, while their independent motions account for the facts of diffusion.

In a solid the molecules are subject to a yet greater constraint, though the general similarity between the volumes of the solid and liquid states for the same substance does not indicate a much closer inter-molecular spacing. They are conceived to oscillate for the most part about more or less fixed positions, with constant collisions with their neighbors. The phenomena of crystallization and magnetism show them to be capable of taking up definite axial directions or 'orientation'; but, being unable to move independently of each other, with any readiness, their assemblages possess rigidity and form.

Nevertheless, molecules in a solid can slowly change their relative positions and may cause extensive alterations in its structure, as in the gradual crystallization of masses of steel where there is a slow segregation and orientation of like molecules from an originally more complex molecular system. The molecules of one solid may travel into the mass of another, as in the mutual diffusions of lead and gold under pressure, and the many instances of 'solid solution'.

Transitional stages exist between the typically solid and liquid states, such as those occupied by pitch, waxes, ice, and many colloids; most solids other than crystals retain some degree of viscous character; while even some crystals show viscosity.

If, for want of more definite knowledge, we assume that molecules are spherical in shape, the diameter of a water molecule is 4×10^{-8} cm., or about two and a half million to the millimetre. The diameter of a hydrogen molecule is about half that of a water molecule; the diameters of complex molecules, such as those of tannic acid, soap, or albumen, are naturally much greater. A cubic centimetre of any permanent gas at $0^{\circ}\text{C}.$ and normal pressure contains 2.75×10^{19} molecules.

GRAVITATION AND MOLECULAR FORCES

The molecules of all substances are subject to both these forces. Gravitation is the force by which all the molecules in a body are attracted by those of another; it varies directly as the masses of the attracting bodies and inversely as the square of the distance between them. Gravitation, of course, is sensible at large distances, matter on the earth being sensibly attracted by the sun 95,000,000 miles away. Gravity is independent of the chemical nature of the substance, a gramme of lead exerting the same attraction on another gramme of lead as it would upon a gramme of lime or water at the same distance.

Molecular attractions are much more intense, but are manifested only over minute distances; consequently, they only come into play when the molecules are brought comparatively close together, and usually become insensible when the distance exceeds the ten-thousandth part of a millimetre, probably much less. Some physicists consider there are grounds for believing it to be of the order of $5 \mu\mu$.² The major limit for the diameter of a water molecule is computed as $0.24 \mu\mu$; therefore for water the radius of molecular attraction must be considerably greater than this, otherwise no attraction could

¹Owing to their extremely frequent collisions and varying angular contacts, the velocities of the different molecules in the same substance, as also the velocity of any given molecule at different moments of time, must vary considerably; the mean velocity, as deduced by statistical methods, is that given.

²The thousandth part of a millimetre, a 'micron', is written ' μ ', and the millionth part, a 'micromillimetre' ' $\mu\mu$ '.

exist between the molecules except when in contact. Johannot has measured an intensely black soap-film just before its rupture, finding it not more than $6\ \mu$ in thickness, or a minimum of 24 molecular diameters.

Much larger limits have been assigned to the radius of molecular attraction; Plateau and Maxwell have suggested $118\ \mu$ and Plateau and Quinke $50.59\ \mu$ for the superior limits. Possibly it may be yet greater in certain cases; thus, in the selective adsorptions between saponin and the minute globules of an oil-emulsion at a water-surface, the latter fail to reach the surface of the liquid by a very small, yet visible, fraction of a millimetre. Again, the 'skins' or films of saponin, albumen, precipitated metals and their sulphides, and of mineral particles adsorbed at a water-surface, may often be of a visible thickness, vastly exceeding those above mentioned. Strong adhesive forces between the foreign particles themselves doubtless aid in the formation of such skins, but in these instances concentration proceeds cumulatively in a manner not easy to reconcile with a very small range of molecular attraction. All we can safely say is that the radius of molecular attraction may vary between $5\ \mu$ and a fraction of a wave-length of light.

Unlike gravitation molecular attraction varies with the chemical nature of the molecules, and there is evidence (lately deduced by Edser) that the variation for different classes of substances is inversely as from the 6th to the 9th power of the distance. Thus for the lower limit doubling the distance between two like molecules reduces the attraction originally exerted by one upon the other to $1/2^6$ or $1/64$. There is thus a steep gradient in the intensity of molecular attraction even within the minute limiting distances through which these are exerted.

It is, however, to these forces of minute range that the properties of cohesion, adhesion, surface-tension, adsorption, etc., are due. While all molecular forces in ultimate origin are probably electrical, nothing is gained, in default of more exact knowledge, by assuming them to originate in this or in any other way; no more, in fact, than the laws of gravitation between masses are affected by the presumed electrical origin of matter.

In a gas, the molecules are so far apart that except at the moment of collision their mutual attractions may be neglected. In liquids and in solids, as we have seen, the molecules are much more closely packed, their attractions constituting cohesion, etc.; but even in solids the vibratory structure remains granular and molecularly porous, their surfaces being therefore penetrable to definite extents by the molecules of gases (gas-occlusion and permeability), of liquids, and in some cases even by the molecules of other solids.

COHESION. The attractive forces exerted on a molecule in the interior of a liquid or a solid by its numerous neighbors are without permanent resultant. Let Fig. 1 represent in vertical section a small mass of water, and the small circles the mean positions of molecules at any moment. If an imaginary plane $A-B$ be traced, the molecules immediately on one side of this will attract those

on the other with the same force as they attract their neighbors, no resultant force tending to move them in any direction. The attractions which they mutually exert across the imaginary plane constitute cohesion.

INTRINSIC PRESSURE. The mutual attractions of molecules on either side of an imaginary plane account for the observed cohesion of a substance; but if no other force existed, and the molecules were at rest, all would mutually draw together until they touched; if we assume the molecules themselves to be incompressible, total incompressibility would result. Experiment, however, shows all substances to be compressible and distensible; the force, statically considered, responsible for the maintenance of the mean molecular distance is termed 'intrinsic pressure', and for solids and liquids balances the cohesive force.

Worthington proved that to produce a given small increase in the volume of a liquid a tension must be applied equal to the compression required for a like diminution in volume; the elasticity of a liquid is therefore the same in tension as in compression. The tensile strength of water is above 11,000 atmospheres, or approaching that of steel; the cohesion of most homogeneous solids and of liquids is more or less of the same order.

Cohesive force has no direct effect upon the mobility

FIG. 1

of the liquid, which permits its adjustment to any configuration provided that the mean distance between its molecules is not altered. That water, in spite of its great cohesion, can be so readily divided into drops is due to mobility; the molecules under an external force such as gravity slide over each other without increase in their molecular distances, permitting, for example, water to be drawn out into a cylindrical column. When this exceeds a length equal to its circumference it becomes unstable, owing to the action of its own molecular surface forces (surface-tension) which molds it into alternate bulgings and constrictions. These develop until the constrictions become infinitely thin, when the column breaks into a series of drops.

Intrinsic pressure being equal and opposite to the cohesive force, determines the mean molecular distance for any solid or liquid; the former resists compression, the latter dilatation. Their effect may be likened to a series of uniform springs connecting the molecules which require the same force to extend as to compress them; the one is

the measure of the other, and both are manifestations of the forces which act between the molecules.

Viewed kinetically, intrinsic pressure results from the molecular collisions arising from the motion of the molecules; being perfectly elastic these lose energy thereby. When they are at their mean distances apart their total energy is potential; as they draw together this becomes kinetic, until completely so at impact. On rebound the energy becomes potential, and so on, similar to the alternations in potential and kinetic energy of a pendulum. All molecules at their interior mean spacing are thus under equal and counterbalanced stress.

Beyond the free liquid surface there are no attracting or colliding molecules, and those in outward motion therefrom will travel on an average further than their mean-path in the interior. It follows that the average molecular spacing in the surface layers is greater than in the interior, and a state of strain is set up. As we cannot conceive of energy without strain, this is one manner of stating the origin of surface-energy; this view of diminished surface density has been maintained by van der Waals.

Wherever molecular spacing exceeds the normal for the substance (liquid or solid) strain will result; an example of the energy manifested by such areas is Mme. Curie's quartz balance, where strains in a quartz plate are produced by weights and give rise to electric charges on the foil-covered surface; or again, electric charges which result from molecular strains produced by expansion on heating crystals asymmetrically terminated ('piezo' electricity). This somewhat less dense and strained condition of the surface layers of solids and liquids has important results in adsorption, to be noted later.

When, as in gases, the forces of attraction are very small, cohesion becomes negligible, and the pressure due to the velocity of the molecules is no longer counterbalanced. One cubic centimetre of water becomes 1700 cc. of steam when evaporated at 100°C., hence the molecules in the steam must be $\sqrt[3]{1700}$ the distance apart, or about 12 times greater than they occupied in the liquid form. If the intermolecular distance be reduced by strong compression, gases show deviations from Boyle's law, especially when approaching their liquefying point, due to their molecular attractions now becoming sensible.

Since the mean distance between the molecules of a gas is large in comparison with their diameter, their mutual attractions being negligible, the actual volume of the molecules will be small in relation to that of the space through which they are distributed.

If we suppose a cylinder fitted with a piston to contain one gramme of a gas of the above constitution, the continued bombardment of the piston by the moving molecules will tend to force it outward, and the force exerted on the piston will be proportional, (1) to the number of molecules contained in unit-volume of the gas, (2) to the square of the velocity of the molecules, and (3) to the mass of each molecule. The number of molecules per unit-volume of the gas is proportional to the density of

the gas, or inversely proportional to the volume, v , of 1 gm. of the gas; it is assumed that the square of the velocity of the molecules is proportional to the absolute temperature T of the gas. Thus, if p denotes the pressure, or force per unit area exerted by the gas on the piston,

$$p = \frac{R}{v} \text{ or } p v = R T,$$

where R is a constant independent of the density and temperature of the gas.

The law derived experimentally by Boyle states that at a constant temperature the pressure of a given mass of gas is inversely proportional to its volume, or that $p v$ is constant; the same result is obtained by making T constant in the above equation. Since T is proportional to the square of the velocity of the molecules, it would be equal to zero if the molecules were absolutely quiescent; the temperature at which this happens is called the 'absolute zero of temperature', and is 273° C. below the freezing-point of water. Thus T , measured from the absolute zero, is obtained by adding 273° to the Centigrade temperature.

In accordance with Avogadro's hypothesis, equal numbers of molecules are contained in equal volumes of different gases at one and the same temperature. Further it has been deduced theoretically by Maxwell, and confirmed experimentally by Perrin, that at a given temperature a molecule of any gas will possess a definite amount of kinetic energy in virtue of its linear motion, this value being independent of the chemical nature of the gas. The force exerted by the impact and rebound of a molecule is proportional to the product of half the mass and the square of the velocity of the molecule, that is, to the kinetic energy due to its linear velocity; since the latter has a value independent of the chemical nature of the gas, it follows that at a given temperature the impact and rebound of a molecule, whatever may be its nature, will exert the same force, whether it be a molecule of hydrogen or one of oxygen, nitrogen, water, or alcohol.

If two cylinders contain equal volumes of different gases at equal temperatures, the number of molecules being the same in both, and the force derived from the impact and rebound of a molecule the same, the pressures are equal, and the product $p v$ will be the same in both cases.

If, instead of equal volumes, equal masses of the two gases are considered, their volumes will be inversely proportional to their molecular weights; for if, respectively, M_1 and N_1 denote the molecular weight and number of molecules in a gramme of the one gas, and M_2 and N_2 in the other, the total mass of gas being 1 gm. in either case, $N_1 M_1 = N_2 M_2$, and $\frac{N_1}{N_2} = \frac{M_2}{M_1}$, the equation $p v = \frac{8.4 \times 10^7}{M} T$ is found to represent the relation between the pressure, volume, and temperature of 1 gm. of any gas of molecular weight M . The quantity $\frac{8.4 \times 10^7}{M}$, generally denoted by R , is called the 'gas constant' of the substance; it is numerically equal to the external work, in ergs, that would be done, as against a movable piston, if a gramme

of the gas were heated through 1° C. under the condition of constant pressure.

In extending this reasoning to liquids it is necessary to allow for a the attractive force exerted between neighboring molecules, which are now very much closer together; and b the finite size of the molecules. As we have seen, the molecules within a certain small distance on one side of an imaginary plane described in the liquid, attract those within an equal distance upon the other side of it, the attractive forces exerted across 1 sq. cm. of the plane being the cohesion of the liquid. If the density of the liquid be doubled, the number of attracted molecules on one side of the plane and the number of attracting molecules on the other side, are simultaneously doubled, the cohesion being increased four times. Cohesion is therefore proportional to the square of the density, or proportional to the square of the volume of 1 gm. of the liquid; it may therefore be represented by $\frac{a}{v^2}$ where a is constant for a given substance.

To take into account the finite size of the molecules it is clear from the equation of $p = \frac{RT}{v}$ that for any finite value of T the pressure can only become infinite when the volume v is reduced to zero. This of course would be possible if the molecules were infinitely small, as they could only come into contact when the volume was reduced indefinitely. If the molecules are of finite size, they will come into contact when the liquid is reduced to some small volume which may be denoted by b ; if the molecules are supposed to be incompressible individually, the pressure must become infinitely great when they are in contact; this condition is complied with if the pressure is equal to $\frac{RT}{v-b}$ instead of $\frac{RT}{v}$.

We can now express the effects both of the cohesion and the finite size of the molecules. Let p denote the pressure exerted on the piston from without; this will tend to compress the liquid. The cohesion $\frac{a}{v^2}$ also tends to reduce the volume of the liquid. Thus the resultant force per unit-area tending to produce compression is equal to $(p + \frac{a}{v^2})$. The internal pressure, due to the bombardment of the piston by the moving molecules, is equal to $\frac{RT}{v-b}$, which tends to press the piston outward and therefore to make the liquid expand. The term 'intrinsic pressure' is generally applied to $\frac{RT}{v-b}$. For equilibrium to exist,

$$(p + \frac{a}{v^2}) - \frac{RT}{v-b}, \text{ or } (p + \frac{a}{v^2})(v-b) = RT,$$

which is van der Waals' equation, applicable not only to gases but to liquids also.

The following table gives the values of the cohesion $\frac{a}{v^2}$ for some liquids; it will be observed that the cohesion, at ordinary temperatures, is generally greater than 10^9

dynes per square centimetre, or 1000 atmospheres. Therefore for pressures in the neighborhood of one atmosphere p may be neglected in comparison with $\frac{a}{v^2}$, so that, to a close approximation,

$$\frac{a}{v^2} = \frac{RT}{v-b}$$

or the cohesion is equal to the intrinsic pressure.

Substance	Molecular weight	Temperature	Cohesion, $\frac{a}{v^2}$ in dynes/cm ²
Hydrogen (liquid)	2.016	-252° C.	3.09×10^9
Argon (liquid)	39.9	-183° C.	1.21×10^9
Oxygen (liquid)	32.0	-188° C.	2.40×10^9
Water	18.08	20° C.	1.23×10^{10}
Pentane	72.1	30° C.	9.00×10^9
Ether	74.1	0° C.	1.11×10^9
Mercury	0° C.	3.55×10^{10}
Ethyl alcohol	46.05	0° C.	3.33×10^{10}
Sodium chloride (fused)	58.5	803° C.	1.148×10^{10}

As the temperature is raised, the expansion of the liquid causes v to increase; the cohesion $\frac{a}{v^2}$ will therefore diminish. Above the critical temperature the cohesion can no longer hold the molecules together in the form of a liquid, and the substance can only exist in the form of gas.

When the temperature is sufficiently high $\frac{a}{v^2}$ may be neglected in comparison with p , and b may be neglected in comparison with v ; so that the equation $p v = RT$ may then be applied without sensible error.

SURFACE-ENERGY AND SURFACE-TENSION

Molecules in the surface layer of a liquid differ from those in the interior by being subject to a resultant force attracting them toward the interior. Let E (Fig. 1) be a molecule in a layer near the surface, and let the dotted circle represent its radius of molecular attraction.

The molecule E will attract all other molecules within this range, according to an inverse power of their distance from it; at the circumference of the circle its attraction becomes negligible. All other molecules surrounding it will act upon it in like manner. But its radius of attraction cuts the surface at JK , beyond which there are no reciprocally attracting molecules. Within the segment of the sphere $JKLM$ the attractions between the contained molecules and E are balanced, but an overplus of attractive force remains, namely, that exerted by the molecules in the interior represented by the shaded segment below LM and equal in amount to the attractive forces missing from the segment above JK . There is therefore a resultant pull toward the interior upon the molecule E .

On the molecule F a greater internal resultant acts, since there are no counterbalancing attractions above it. The attraction toward the interior thus increases as a molecule approaches the surface, and there reaches its maximum. If a molecule be moved from the interior to the surface, work must be done against the resultant attractions; hence on reaching the surface it will possess potential energy in excess of that which it possessed in

²An atmosphere, 76 cm. mercury at 0° C. = about 1.033 kg. or 1,013,250 dynes per sq. cm.

the interior, just as a weight raised against gravity acquires potential energy.

The foregoing can be regarded only as the simplest possible statement of the molecular theory accounting for surface energy; its further development necessarily becomes more complex. Thus the unwieldy molecules of albumen, tannic acid, or soap, containing hundreds of atoms arranged in complex molecular groups, will differ greatly in mass, configuration, and resultant attractive force from a comparatively simple molecule like alcohol, and the nature of the resultant attractions of such an assemblage of molecules can scarcely be conjectured.

Neither can the simpler types of molecule be supposed to possess invariable or like configurations, or to exert uniform attractions in all directions. Probably each has its characteristic axes; differences in the polarity (or like orientation) of a mass of molecules account for the variation in physical properties shown by unlike faces or cleavage-planes of the same crystal.

Even water itself may not consist simply of molecules of H_2O , but of 'associated' molecules, $2(H_2O)$, $3(H_2O)$, and possibly yet more complex 'hydrones'; Taubmann has shown that water on freezing can be made to yield ice fractions of differing properties, regarded as the congelations in differing proportions of such associated molecular groupings.

As all molecules in a surface layer possess more energy than those in the interior, the total potential energy in a unit-area of surface is termed the 'surface-energy' of the substance; and because any system always tends to arrange itself so that its potential energy is at the minimum for the circumstances, the free surface bounding a liquid will be such that its area is minimum. The chief exhibition of this surface-energy of a liquid is the phenomenon of surface-tension which acts as if the liquid were encased by a uniformly contractile film. This, in satisfying the condition of minimum energy, or surface, causes falling drops of liquid to assume the spherical form. It is manifested by the resistance of a liquid surface to rupture; by the force such a surface when anchored against enclosing walls exerts in supporting a thin column of its own liquid, or 'capillarity'; by the mechanism whereby comparatively weighty particles are suspended at a liquid surface; by adsorption, and other effects.

Since surface-tension strain results from the unbalanced forces existing at the surface, it must be in some fundamental relation to the magnitude of the internal balanced forces or stresses; that is, to the cohesion or intrinsic pressure of the substance. This relationship is proved to exist; substances which have low compressibility, that is, high intrinsic pressure, possess high surface-tension and the reverse.

Liquid	Surface-tension in dynes/cm.	Coefficient of compressibility in dynes
Mercury	440	3.83×10^4
Water	75	48 "
Glycerine	65	52 "
Benzine	28	92 "
Alcohol	21.6	105 "
Acetic acid	23	88 "
Ether	16	190 "

†Surface-Tension and Surface-Energy, Willows and Hatchesek.

The compressibility of metals and solids is lower than for liquids.

The contractile forces due to surface-tension may be visualized by dusting a water surface with lycopodium which rests upon it without being wetted, and then touching the water with a trace of some liquid of lower tension such as alcohol, oil, or even the greased finger tip; the lycopodium will flash away in all directions from the point of contact, as the higher-tensioned water surface pulls out the less resistant contaminated film of lower tension.

Surface-tension differs from the tension of a film of india rubber, since the latter increases by stretching, whereas that of a pure liquid remains constant and cannot be increased by stretching. The molecules retain their original spacing at the surface; increasing the area merely results in bringing more molecules from the interior to satisfy the enlargement of the surface; these then take up the spacing common to the other surface molecules.

Surface-tension (represented by σ) is therefore definable:

1. As the energy expressed in ergs required to create a fresh surface of 1 sq. cm. (unit-area); this for water is 75.8 ergs. Alternatively:

2. As the force equal to the total molecular attraction exerted across a line of 1 cm. in length on the free liquid surface; for water at $0^\circ C$, 75.8 dynes per cm. Gravity being 981 dynes per gramme, at London, the dyne is roughly equivalent to the weight of a milligramme.

Surface-tension is not equal to the total energy of the unit surface, since in the creation of a fresh surface heat is also absorbed. If the new unit-surface is to maintain the original temperature (the 'isothermal' condition), heat energy enters the surface and is stored there. A newly-formed surface of water of 1 sq. cm. absorbs heat equivalent to 41.5 ergs; hence the total surface energy of water at $0^\circ C$, is equal to 117.3 ergs per sq. cm. If the surface be enlarged 'adiabatically' (where no heat enters or leaves the water) the liquid will be cooled.

Surface-energy cannot be regarded as completely concentrated at the immediate surface; it reaches its highest value there, and becomes inappreciable at a depth probably equal to the molecular range of attraction for the particular liquid; below this distance the molecular constitution of the liquid will be that of its general interior mass. It is within the surface layer that certain molecules or particles foreign to the pure liquid tend to be concentrated; such will reach their greatest concentration at the actual surface. This process of surface-concentration is known as 'adsorption'.

Among liquids, mercury and the molten metals have the greatest surface-tension, a fact of interest when considering the probable magnitude of their solid surface-tensions.

The surface-tension of a liquid can be accurately measured by weighing the pull exerted by a film of the liquid.⁵ The method of capillary height gives a true figure only

⁵See 'General Physics for Students', E. Edser.

when the liquid completely wets the walls of the capillary tube—contact angle 0° —a condition not always obtainable.

Approximate surface-tensions of some other liquids against air:

	Dynes/cm.		Dynes/cm.
Molten copper	1178	Phenol (41°C.)	37.0
gold	1018	Cresol	34.8
silver	858	Olive-oil	32.0
zinc	707	Petroleum	27.7
tin	520	Duopne (terebene)	25.9
aluminum	480	Turpentine	23.6
lead	424	Chloroform	26.6
bismuth	346	Acetone	23.0
antimony	274		

MODIFICATION OF SURFACE-TENSION

a. Surface-tension decreases with rise in temperature, and disappears at the critical point of the liquid, when the surface of the liquid becomes merged in its gas.

For water at 0°C , $\sigma = 75.8$ dynes/cm.; for each degree centigrade rise in temperature the tension decreases by 0.152 dyne/cm.; hence for any temperature the tension will be $\sigma - 0.152 \times t$.

b. Surface-tension is influenced by the curvature of the surface, its value becoming somewhat less for a concave surface (an air-bubble in water) or for a convex surface (a drop) than at a plane surface. It is however only when the radius of curvature is very small that the surface-tension is diminished perceptibly.

PRESSURE IN BUBBLES

Owing to surface-tension, a liquid surface tends to contract; and if the surface is curved, a pressure acting toward the centre of curvature will be produced. Surface-tension in the water-film surrounding an air-bubble therefore increases the pressure on the air until this reaches equilibrium with the compressive force; hence the air contained in a bubble is always at a pressure higher than that of the surrounding atmosphere. The sharper the curvature the greater will be the compressive effect, the excess pressure, P , being inversely proportioned to the radius of the bubble. For a submerged bubble (neglecting pressure due to hydraulic head) $P = \frac{\sigma \times 2}{r}$; for a bubble in air, the walls of which has two surfaces,

$$P = \frac{\sigma \times 4}{r}.$$

As the diminution in the value of σ also due to curvature is of a much smaller order than the increase in pressure due to curvature, very considerable compressions are reached in small gas bubbles. In one of 0.001 mm. radius, which will rise through water at about 1 mm. per second, the air is at an excess pressure of about one atmosphere.

c. The surface-tension of a liquid is profoundly modified by adsorption.

Pure water will not form a persistent air-bubble, nor a froth. Indeed a stable film, and therefore a froth, cannot be produced from any pure or homogeneous liquid whether water, alcohol, ether, etc.; this will require further mention under 'adsorption'.

d. An electric field normal to the surface of a liquid

diminishes surface-tension, since the tension of the lines of electrical force acting outward across the air/liquid surface diminishes the resultant of the unbalanced molecular forces which act toward the interior of the liquid; such electrical effects however appear to be negligible in flotation practice.

(To be continued)

Graphite in Madagascar

Producers of graphite in Madagascar have taken heed of the demand for a higher grade and have directed their energies toward improvement in quality rather than increase in quantity, according to R. B. Ladoo, of the U. S. Bureau of Mines. The decrease in demand since the close of the War has made this step both necessary and expedient. Recent analyses at Tananarive show 87 to 90% of carbon, and even 93 to 95% is reported by some companies, in contrast to an average of 80 to 82% in 1916-17. Most of the small mines have been compelled to close down on account of lack of demand and lack of shipping space, while the larger companies have continued, but on a greatly reduced scale. It seems probable that at the present rate the 1919 production will not exceed 6000 tons. Labor conditions are reported difficult and transportation facilities inadequate, so that even with an increased demand maximum production could not be quickly attained.

As there are no refining mills in Madagascar, graphite is shipped practically as mined. Thus a statement of shipments by grades is impossible. From statistics available it would seem that but one shipment was made in the first six months of 1919. This was 28 tons from the port of Tamatave, shipped to France in the second quarter.

In July 1919 it was estimated that the following stocks were held by producers and exporters in Madagascar:

Grade (per cent carbon)	Tons
78-80	5500
80-83	8250
83-87	8250
87-90	3300
Above 90	2200
Total	27,500

Prices quoted in July 1919 for 90% carbon, f.o.b. ship, Tamatave, averaged \$0.048 per pound. The American graphite industry at present need expect no large imports of Madagascar graphite. The Morgan crucible interests, formerly the largest buyers of Madagascar flake, have cancelled all their contracts with the miners. The French demand has been greatly reduced and Madagascar shippers do not feel that at present prices they can compete with Mexican graphite in the United States markets. The imports of graphite for September 1919 show a very large increase over those of the same month in 1918, and the indications are that the total imports for 1919 will be 50% higher than in 1918. The following figures are based upon reports from the Bureau of Foreign and Domestic Commerce:

	Tons	Value	Value per pound
September 1918	1095	\$192,753	\$0.088
September 1919	8322	1,137,449	0.068

Imprisoned Underground

By GEORGE HUSTON

To be imprisoned for over two weeks in the cross-cut by a cave underground and to be rescued unhurt was the remarkable experience of two miners, Peter Grant and Emil Sayko. The accident occurred at 10:45 a.m., November 15, in the Gold Hunter mine, situated on the outskirts of Mullan, Idaho, in the Coeur d'Alene region. Both men had families in the town.

The cave happened in what is known as the north-west stope, an extension of the Ryan stope. The old Ryan workings had caved in 1913, being filled thereby to the 33rd floor, leaving an opening between the top of the debris and the roof. The roof had not been penetrated,

nearly vertical or slightly south. The practice was to timber close to the stopes, to hold the slabby walls apart, then fill for safety, afterward. In this case, the extension stope, consisting of 35 floors, had been filled from the 3rd to the 22nd, excepting three 6 ft. sets that were used for a man-way, timber-slide, and chutes. From the 28th floor up, it was only a raise. The 18-ft. prospect cross-cut in which the men took refuge was on the 26th floor. From the third floor down to the tunnel-level the stope was supported on stulls, and as no stoping had been done below the tunnel-level, the stuffed ground was not damaged by the cave.

60 ft. of solid rock intervening between it and the old level above. The extension stope had not been worked for several months, and the two men were cleaning up preparatory to taking a contract for a raise through. They had finished, and were descending, when Sayko noticed a crack on one of the walls. Becoming alarmed, he climbed a few floors for his carbide and water. On descending again, he had a slight argument and prevailed on Grant to go back for his lunch-bucket. The delays undoubtedly saved the men's lives, for on descending a few floors more, a cap snapped in front of them. They then made all haste to reach a 45th foot-wall prospect cross-cut, barely entering it in advance of the cave, which was thundering behind them.

The Hunter lode is in a wide zone of fissuring, shearing, and sheeting, which crosses the strike of the thin-bedded Wallace formation. The dip of the fissuring is

What caused the cave was the slipping down of a huge wedge-shaped slab running parallel to the length of the stope, adjacent to the timber, and extending down to the eighth floor; the bottom lodged against the filling, while the top fell over and smashed the upper timbering of the stopes, the subsequent movement effectually sealing all the connecting openings.

Every means was tried to reach the men through old workings, but these were found to be blocked. An incline-raise from a safe floor was started toward the west end, where the extension stope was known to be narrowest, but it became apparent soon that all the chutes were closed and that no openings existed. Efforts were then concentrated on getting up through the muck-pile to the top by the quickest route. The rescue-crew knew the men were alive from faint rappings and the smell of wood-smoke resulting from their efforts to keep warm.

At this juncture the Bureau of Mines at Washington was asked for the use of the new device, the geophone, for locating noises incidental to operations of this nature. The Bureau responded at once, directing two experts at widely separated points to report at Mullan, and the apparatus and men arrived as fast as the railway could bring them. In the meantime the men had been reached by a drill-hole, but the mere fact of the ready acquiescence of the Bureau and the sending of some of their best talent gave a high degree of encouragement to the hard-pushed crew and management.

After working six days on the raise, reaching about the 24th floor, through the muck-pile, the whole mass started to move, closing the mouth and other portions of the rescue-raise, imprisoning two men, Jack Delmarh and James Collins of the rescue-crew.

It was hardly thought possible, in view of the movement of big slabs of rock and fine material, to find Delmarh and Collins alive, so a feverish search for the bodies began. After six hours of strenuous work the men were heard talking. They were removed unhurt, after 15 hours imprisonment.

But the settling left the search for Grant and Sayko where it had started, it being evident that raising through the muck was too dangerous and slow, and that the men would perish before being found.

A raise was started immediately in solid rock at the west end of the stope, utilizing the latter to break against, and spilling against the muck. This method favored safety and speed, but the distance was nearly one hundred feet, and some coincident operation had to be carried on to sustain life in the men, who had now been imprisoned for six days.

There being a 1½-in. diamond-drill outfit on the ground, the Diamond Drill Contracting Co. of Spokane was called by telephone to furnish a crew, which arrived on the next train. A hastily improvised hoist lowered the outfit to the top of the 60 ft. of solid rock capping the Ryan stope, and on November 21 at 8 p.m. drilling was started, the 60 ft. of drilling being completed in 15 hours.

The drill-crew and management were ignorant of the exact position of the imprisoned men. To avoid end-projections of the stope and filling, the hole was drilled vertically into the Ryan stope, instead of on an incline to reach the cross-cut. When near the bottom the hole lost its water, the seepage attracting the attention of the imprisoned miners. They scrambled in the direction of the seepage with a lunch-bucket, catching the first drink that they had had for four days. After breaking through, the drillers lowered a half-inch galvanized pipe, which struck Grant on the head. The overjoyed man shook the pipe vigorously, conveying the information to those above that their efforts had not been in vain. A whistle had been attached to call the men, and after its removal communication was opened up.

One of the first things for which they asked was light, so a wire was passed down outside the pipe, with a two candle-power bulb, taking current from a storage-battery. The pipe, after being warmed by flushing with

hot water, served to convey soup, stimulant, milk, etc. The company's physician prescribed the diet, and the hungry men were made as comfortable as possible. Meanwhile another hole was drilled and reamed out to two inches. Through this, elongated loaves of bread wrapped in paraffined paper were passed and suitable receptacles filled with finely chopped fruit, vegetables, and meats were forced.

On account of the danger from further caving, a two weeks stock of provisions, candles, and other things was lowered and conveyed to the cross-cut; also the ½-in. pipe was extended and the men were instructed to stay there until rescued. With plenty to eat and drink, and means of warmth, the question of sustenance was solved.

Meanwhile the work of raising went on with strenuous energy, day and night, until on November 29 at 3 p.m. the men were removed, after being confined for 14 days and 4 hours in their underground prison.

It is pleasing to record that the resources of the entire district were placed at the disposal of the Gold Hunter management. With characteristic brotherly feeling, the workers engaged in the rescue gave of themselves freely and without stint. The rescued men, after having their eyes bandaged, were conveyed to the hospital at Wallace. They were in good condition, and thanks to their pluck and powers of endurance, will soon be out in good health. Their faithful wives, who sustained the men's courage after communication was opened, are the happiest of women, never losing their faith in the ultimate rescue.

WHAT IS A NUISANCE? "That's the greatest nuisance that ever came out of Mexico," said a Texas rancher several years ago, with a sweep of his arm. Many nuisances have come out of Mexico, including boll weevil and Villa, but what the rancher referred to as the greatest of them all was the *candelilla*, a rank weed covering northern Mexico and millions of acres of southern Texas. The cattle-men would rather see good grass growing, on which steers might fatten, but this weed defies extermination. Cut it off at the roots, and the next year its growth is as luxuriant as ever. Perhaps Modern Industry heard the rancher's remark, for one day she summoned her hand-maiden, Chemistry, and commanded her to find the Creator's purpose in placing the weed there in such abundance. After patient research, Chemistry placed in the hands of her mistress a little cake of hard wax almost equal to the carnuba made from the wax palms of Brazil, and worth about \$500 per ton. Its earliest use was for varnish, floor-wax, and candles; but now the making of phonograph records claims an increasing share of it. As the cost of manufacture from the *candelilla* is not large, Modern Industry asks, "What is a Nuisance?"

Selenium production in 1918, according to the U. S. G. S., was 103,694 pounds, valued at \$206,540, an increase of 162% in quantity and 195% in value as compared with figures for the previous year. Of the quantity sold during 1918 about 60% was used as a coloring and deoxidizing agent by the glass industry.

The Como Consolidated Mill

BY E. BORZYŃSKI

The Como Consolidated Company's property is situated in the Silver City-Palmira mining district of Lyon county, Nevada. The mine and mill are about 12 miles south-east of Dayton, the nearest railway point. The mill has been recently remodelled and enlarged to treat the ores from the Como-Eureka, North Rapidan, and Lucky Sunday mines.

The ore consists of hard quartz with small amounts of

is approximately 100 tons per 24 hours. Only about 60 tons per day is being milled now, but the management expects to run the mill to its full capacity as soon as the ball mill is ready for operation.

The ore from the mine is dumped into a 60-ton bin. It is then reduced to one inch in a No. 3 McCully crusher and elevated by a bucket elevator to a 75-ton bin. The crushed material is fed by two Challenge feeders to ten 1050-lb. stamps. The stamps make 110 drops per minute. Three to five mesh discharge screens are used. The capacity is about six tons of ore per stamp per 24 hours.

The ore fed to the 5 by 5-ft. ball-mill will be delivered from the fine-ore bin onto a 20-in. conveyor. The belt has a variable speed, so that the rate of feeding can be regulated at will. To the ball-mill is connected a 4½ by 16-ft. duplex Dorr classifier working with the ball-mill in closed circuit. The ore is to be reduced from one inch to 85% minus 200-mesh in one operation. The overflow from the classifier will join the overflow from a 4½ by 22-ft. duplex Dorr classifier working in closed circuit with a 5 by 18-ft. tube-mill, and the united overflow will be pumped by a 2-in. centrifugal pump to the No. 1 Dorr thickener.

The pebbles used in the tube-mill are made from local material. One of the mine stops contains a large number of very hard and tough quartzite boulders, which are separated at the coarse crusher and broken up in a sledge-hammer to the required sizes. About 10 lb. of pebbles per ton of ore is required, and although consumption of these pebbles is high, the grinding results are satisfactory. The cost of

the pebbles is $1\frac{1}{2}$ cents per ton of ore milled, and is much lower than the cost of Danish pebbles. Besides the home-made product contains about \$7 per ton that is recoverable.

The No. 1 thickener is 30 by 10 ft. and the mechanism makes 12 r.p.m. Most of the overflow is sent by gravity to a clarifier and the remaining flows to the stock-solution tank.

The clarifier-tank is 20 by 10 ft. and contains eighteen 8 by 5-ft. leaves. The leaves are connected to a 9½ by 8-in. vacuum-pump and the solution so clarified flows to

FLOW-SHEET OF COMO MILLS

calcite and other minerals. The valuable metals are gold and silver in approximately equal proportions, and both are so minutely disseminated that fine grinding is essential. The milling process consists of crushing in a gyratory machine followed by stamps and a ball-mill, both crushing in a 3½-lb. cyanide solution. The pulp from the stamps is classified and the coarse material re-ground to 85% minus 200-mesh in a tube-mill. The ball-mill will reduce the ore to the required fineness in one operation and is so arranged that it can be used as an intermediate grinder in place of the stamps. The capacity of the mill

two 10 by 10-ft. gold-tanks and from there to nine 8-compartment zinc-boxes. The zinc heads average \$1.50 per ton in gold and silver, and about 3.5 lb. of cyanide. The zinc tails flow through measuring orifices into a 20 by 8-ft. sump-tank.

The overflow from the No. 1 thickener is raised with an air-lift into four 12 by 36-ft. Pachuca agitators. The air for agitation is supplied by two 10 by 12-in. compressors at 25 lb. per square inch. The thickness of the agitated pulp is 33% solid. Cyanide is added to the No. 1 agitator, where the solution is raised to 4 lb. of cyanide per ton of solution.

The discharge from the No. 4 agitator flows to the No. 2 thickener. This is 30 by 10 ft.; here the pulp is washed by the addition of the filtrate from the Oliver filters and

MAP SHOWING POSITION OF COMO, IN NEVADA

the overflow from the No. 3 thickener. The overflow from the No. 2 thickener goes to a 20 by 10-ft. stock-solution tank, and the underflow to the No. 3 thickener for further washing and thickening.

The No. 3 thickener is 24 by 10 ft. Here the pulp is washed with barren solution from the sump-tank; the thickened overflow of about 55% solid flows by gravity to 12 by 12 ft. and 8 by 12 ft. Oliver filters where it receives final washing and dewatering. About 19 tons of fresh water is used per 24 hours, this being sufficient to replace the solution lost in the tailing. Only one filter is used at a time, the other being kept in reserve.

The consumption of cyanide is nearly 2 lb. per ton of ore. Eighty-nine hundredths of a pound is the mechanical loss, the remainder being chemical. The chemical loss is exceptionally high owing to the copper content of the ore. The amount of lime used, however, is very small, owing to the low acidity of the ore and its fast-settling rate. About one pound of lime per ton of ore is all that is required.

Charles La Kamp is the general superintendent and Mr. Warner the mill superintendent. Their combined efforts are producing good results. The milling cost, at first high, steadily diminishes, and is near the \$2 mark at the present time, which is very good for the locality and existing conditions.

THAT the personnel of the U. S. Geological Survey is facing serious deterioration is indicated by the following statement of the Director of the Survey in his annual report: "The fact that there have been 77 resignations from the scientific force of the U. S. Geological Survey during the last year—17% of the force—suggests inadequacy of compensation, and the percentage of resignations in the clerical and non-scientific force was even larger. This statement, of course, does not include separations to enter military service. The largest inroad upon the Geological Survey personnel comes from the oil companies; the final result of the pioneer work of the Federal geologists in applying geologic methods to the search for oil and gas is that a large proportion of the leading oil geologists the world over are U. S. Geological Survey graduates. Indeed, the future decline in popularity of the Geological Survey as a recruiting station for oil-company employees will be due simply to the fact that the experienced oil geologists who remain in the Government service are from personal preference immune to outside offers. The relation between Government salaries and outside salaries of geologists has been definitely determined in a compilation of the records of 29 geologists who left Government service after receiving an average salary of \$2271. The average initial salary of these men in private employ was \$5121, and after about two years of average service this compensation averaged \$7804, and eight of these geologists receive \$10,000 or more. The disparity is even greater if consideration is given to the large financial returns from investments made by the private geologists in connection with their professional work, a privilege properly denied by statute to the official geologist. That the value of these men as specialists and consulting geologists is far greater to the country at large than to private corporations is undeniable. Furthermore, it is important to note that most of these geologists had persisted to the limit of endurance with a magnificent spirit based on their love of scientific research and their desire to contribute to the sum of geologic knowledge. Most of them have been forced out of the service by sheer financial necessity. Unless adequate measures are taken to ameliorate the situation, the geologic staff is destined to suffer far greater deterioration of morale and depletion in its ablest, most responsible, most experienced, and most valuable members. The Geological Survey is passing into a stage when, with greater need than ever for systematic geologic work in the country, it is ceasing to be attractive to the young men of greatest ability, training, and promise. This situation deserves prompt and effective remedy, for it threatens most seriously to cripple this branch of the public service."

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

PHELPS DODGE POLICY OUTLINED BY NEW GENERAL MANAGER.—HIGH-GRADE ORE AT SHEA COPPER PROPERTY.

DOUGLAS.—P. G. Beckett, who became general manager for the Phelps Dodge company on January 1, believes that the copper situation is somewhat more cheerful now than 60 days ago; 18 and 18½ cents, however, is incommensurate with the present cost of production, based upon wages at 24 cents under the sliding scale and with over-

worked off and there is sufficient demand to justify us in resuming production. Similarly, at the Burro Mountain branch, Tyrone, N. M., no production will be made by the recently remodeled concentrator until the demand for copper and financial conditions justify it. At the Moctezuma Copper Co., at Nacozari, Sonora, production will be continued on a 50% basis and a few necessary improvements will be made in and about the mine. Plans are in hand for remodeling the concentrator to treat a larger tonnage with improved metallurgical results, but

THE ARIZONA DESERT IN BLOOM; THE SUPERSTITION MOUNTAINS IN THE BACKGROUND

head charges high as a result of decreased production. It will be the policy of the Phelps Dodge Corporation to maintain uniform curtailed production. Mr. Beckett says it is up to each individual, whether working with hands or head, to produce individually as much as possible. "At the Copper Queen branch at Bisbee no material change is contemplated, either underground or on the surface," said Mr. Beckett. "The smelter will continue examinations and test work now under way, but no new construction is in sight while present conditions last. At Morenci the present campaign of development work to open new orebodies will continue during the present year, but though plans for a new concentrator will be made, nothing will be decided definitely and no money expended until the present big copper surplus has been

most of this work is contemplated for the latter part of 1920 rather than at the present time." Mr. Beckett comes here to succeed A. T. Thomson, assistant to the president, who has gone to New York.

The Colford Copper Co., operating a group of claims adjoining the Swisshelm gold-silver property, 30 miles north of Douglas, is installing an experimental mill, including two Wilfley tables, a ball-mill, crusher, and a distillate engine. The company has a quantity of lead-vanadinite ore blocked out as well as some gold, silver, and lead carbonates. The operating company is an Alabama corporation, headed by Alexander Cole as president. E. A. Hemphill is manager.

TOMBSTONE.—In order to operate the Humboldt mine near Hill Top in the eastern part of Cochise county, sev-

eral Tombstone men formed a leasing company at a meeting here. The mine is 14 miles from the Southern Pacific railroad, Dos Cabezas being the nearest station. The property has been thoroughly sampled with satisfactory results. Henry Bonardiman, superintendent, is preparing to start work. There is some machinery already on the ground but it is said the equipment will be increased soon.

FLUX MINE.—The management of the Flux mine reports approximately 100,000 tons of lead-silver ore, about 60,000 of which is lead carbonate, blocked out. A winze sunk from the 160-ft. to the 260-ft. level is entirely in sulphide ore. All necessary material for a ready-fluxing smelter-charge is on the ground, including manganese, iron, lime, and silica. Nearly a mile of underground work has been completed. The ore averages from 1 to 7 oz. silver and from 11 to 18% lead per ton. There is a 100-ton flotation mill on the property, and the construction of a smelter to treat ore and concentrate is being given consideration.

JEROME.—Shea Copper Co. has almost completed the temporary ore-bins at the foot of the dump and a road has been built to give easy access to the bins. With completion of the road and bins shipments of 25 tons of high-grade silver-copper-gold ore will be made daily to the United Verde Extension smelter. Very good ore is being found in the raise from the 320-ft. level at the intersection of the east-west and north-south veins. The general average is said to be about \$250 per ton, with silver predominating. The raise at last report had been carried up almost 100 ft., practically all in ore and with no sign of a wall. Good progress is being made, according to those in charge.

TUCSON.—C. M. Taylor and associates have taken over the group of mines at Olive camp in the San Xavier district south of Tucson. These mines were originally opened in 1886 and yielded a large tonnage of silver ore. Lessees at various times have opened high-grade pockets of chloride silver and lead ore. Mr. Taylor will work part of the property and part will be leased.

YUMA.—J. M. Pryor has sold his group of five claims in the silver district 30 miles north of Yuma to Los Angeles and Salt Lake operators for \$70,000. The vein was discovered a year ago and on sinking widened to 28 in. of rich silver ore.

PATAGONIA.—J. M. Layman, owner and operator of the Blue Nose silver property, has announced his intention to organize the Arizona Patagonia Silver Mining Co. to take over this property. Development during the past seven months has opened a large tonnage of ore. The Blue Nose mine has been worked irregularly during the past 30 years and has produced some rich ore.

Shipments of 300 tons of good-grade ore are being made monthly from the Mowry mine. A large body of milling ore is being developed and it is expected that in the near future sufficient ore will be assured to warrant a mill. Since operations commenced in 1918 only virgin territory has been developed. There is known to be a large tonnage of milling ore in the old workings.

COLORADO

1919 PRODUCTION IN CRIPPLE CREEK DISTRICT.

CRIPPLE CREEK.—Production from the Cripple Creek district for 1919, curtailed first by the labor trouble and more recently by the coal shortage, is the lowest since 1895, when the camp was in its infancy. In that year the camp was credited with the production of gold ore worth \$6,100,000. In the past year the mines have produced and the mills have handled 756,000 tons of ore with an average value of \$9.82 and gross bullion value of \$7,439,719.59. In previous years the bullion value of the ore has at times exceeded \$12,000,000. January was the best month, with a production of \$735,000, while in November but 33,182 tons, with a bullion value of \$292,738, was treated.

Considering the total production the dividends distributed were satisfactory. Four companies contributed a grant total of \$2,060,000 paid stockholders. In addition to this amount, lease profits, conservatively estimated, totaled \$400,000. The companies and their dividends follow: Cresson Consolidated G. M. & M. Co., \$1,220,000; Golden Cycle M. & R. Co., \$540,000; Portland G. M. Co., \$240,000; Vindicator Consolidated G. M. Co., \$60,000.

The output of the district by months was:

Month	Tons treated	Gross bullion value
January	82,510	\$735,150.70
February	75,350	647,500.00
March	74,643	737,784.72
April	78,500	674,715.00
May	65,376	691,861.45
June	62,900	648,893.00
July	66,162	636,828.40
August	55,930	614,937.66
September	60,590	590,255.60
October	53,071	612,804.48
November	33,182	292,738.58
December	48,000	566,250.00
Total	756,214	\$7,439,719.59

MAYDAY.—E. B. Miller, superintendent of the Cumberland, recently let a contract to Graff and Rudolph to drive a 100-ft. tunnel into Snowstorm mountain on the Cumberland vein, and they have opened up a rich 4-in. streak of gray copper. The Cumberland vein, which is 3 to 5 ft. wide, has been explored in a number of places with long tunnels and open-cuts. One 1600-ft. tunnel has the vein exposed for a distance of 1200 ft. The Cumberland is among the oldest producers of the district, but has been idle for a number of years. A mill on the property, which was not a success, will be remodeled according to present plans.

Carl Bowman, who is interested in the Jumbo, has secured a sub-lease on the Little Nona from Eli Blunt and will begin operations there, it is said. The Nona claim is contiguous to the Jumbo where an orebody was recently opened. The Nona has been operated entirely by lessees and has produced approximately \$18,000.

LEADVILLE.—The Arkansas Valley smelter is operating

at 50% capacity with three blast-furnaces in service. The Leadville mines shipping to the smelter and their approximate tonnage follows: Yak tunnel, 80 cars; Down Town group, 120; Hbex, 30; Iron mine, 15; R. E. Lee, 10; Matchless, 12; Denver City, 8; Adelante, 8; Mikado, 6; and scattered leases, 60 to 70 cars.

TELLURIDE.—For the first time in 15 years the Tomboy Gold Mines, Ltd., passed its dividend. More ore was treated than during the previous 12 months, but the realization was less. In commenting on income-tax levies, the chairman of the board at the annual meeting in Lon

THE IDAHO MINE, NEAR MAYDAY, COLORADO

don said: "We have become liable to pay income tax in the United States, and the authorities there, recognizing that our mine is a wasting asset, in a spirit of justice, meet us very fairly, and make us an allowance on all the ore we take out. I cannot pass from this subject without contrasting the treatment we receive from our own Government in collecting income tax. It makes no allowance for anything taken out, with the result that we shall have to pay income tax not only on our profits but on the whole capital invested in the mine. The cash assets have been left almost entirely in the United States to pay for our flotation plant."

DENVER.—A call has been issued by George M. Taylor, president, and M. B. Tomblin, secretary, for the seventh annual meeting of the Colorado Metal Mining Association, to be held at the State Capitol building January 20, 21, and 22. Burdensome taxes, tariff legislation, industrial insurance, and readjustment of freight rates are some of the problems that are to be discussed. The third annual meeting of the Colorado Chapter of the American Mining Congress is to be held in conjunction with the association meeting.

NEVADA

DEVELOPMENTS AT DIVIDE PROPERTIES.—MISCELLANEOUS NOTES.

DIVIDE.—In a drift being driven south from the west cross-cut to the vein, on the 200-ft. level of the Divide Extension a 4-ft. face of ore assaying \$930 has been opened, according to an official statement. Engineers now are confident that the Divide Ex. shoot will be found in the Brougher at or below a depth of 300 ft. The new shaft of the Belcher Extension has reached the 100-ft.

point, where a station is being cut preparatory to starting lateral work to determine the width of the vein and length of the ore shoot. On the 85 ft. level of the main Belcher Extension shaft the Belcher is driving east toward the boundary line between the two. The Belcher also is driving cross-cuts north and south from its main shaft. The Victory is working at several points, the most important being north-west of the shaft on the 200 ft. level, where a drift is being driven toward the intersection of a cross vein with one striking north east from the Butte. The Victory, Belcher, and Belcher Extension are exploring the main vein of the district as it continues north-west from the Brougher. This vein has been traced into the Thompson and Pay, north-west of the Belcher Ex. The Dividend, north of the Brougher and north and east of the Divide Extension, has drifted 125 ft. east from the No. 2 inclined shaft sunk in a vein striking east, near the intersection of this vein and the Divide Extension vein.

GOLDFIELD.—The Black Butte, in the Diamondfield part of the district, has been closed because of lack of funds until such time as the Orizaba, 35 miles north-west of Millers in Nye county, owned by the Black Butte, has been sold under an option or the option is relinquished. If the Orizaba is sold the sale will provide funds for further work and if not an assessment may be levied. Raising continues in the vein recently found on the 500-ft. level of the Red Hill, but only low-grade ore is being found. The Cracker Jack has levied assessment No. 8, at the rate of 1½¢. per share, delinquent January 31.

ROUND MOUNTAIN.—The Nevada Silver Shield Mining

OUTCROP OF PRINCE VEIN, ARROWHEAD MINE, NYE COUNTY, NEVADA.

Co. has been organized to develop the Silver Shield mine in Horse canyon. According to officers of the company 200,000 tons of silver ore assaying from \$15 to \$18 has been proved in a 400-ft. tunnel reaching a depth in the vein of 160 ft. After the company has been financed it is planned to drive a second tunnel to cut the vein at from 350 to 400 ft. Springs on the eight claims owned by the company will furnish ample water for a mill. The Silver Shield Extension Co. has been organized to develop claims adjoining on the strike of the vein.

ARROWHEAD.—Raising from the east drift on the 175-ft. level of the Arrowhead has been stopped without entering the vein and drifting has been resumed. It is estimated that an additional 75 ft. will be necessary to reach the vein. Work is being done slowly, as the hoisting equipment is of limited capacity. It is reported that the terms of the sale will not permit the shipment of ore pending the making of a payment due in the near future. General conditions in the mine are said by engineers to be excellent.

WEST DIVIDE.—No work has been done in the West Divide for several weeks. L. L. Patrick, manager, is in San Francisco and it is reported that a deal for financing the company on a larger scale is pending. Mine conditions were good when work was stopped, but a tunnel was being driven in a full face of quartz, making driving extremely slow with hand-drills, and it is reported that one of the purposes of the manager's trip to San Francisco is to secure money for buying an air-compressor.

OREGON

PLACER MINING IN SIXES RIVER DISTRICT.

SIXES RIVER DISTRICT.—An important recent development in this district is the opening of placer mines by the Inman Mines Co. The company recently completed a dam on Sixes river, 35 ft. high and 135 ft. long, which will retain about 6,000,000 cu. ft. of water. A 34-in. wood-stave pipe-line has been built with a vertical fall of 147 ft., and three hydraulic giants, with 6-in. nozzles are now at work. According to the estimate of the company's engineer the project will develop 3000 hydro horsepower. The company proposes to erect an electric power plant for mining and lighting purposes. This district is situated in the northern part of Curry county and occupies the area drained by the Sixes river. The climate is mild, and the annual rainfall varies from 65 to 70 in. Snow rarely remains in the lower altitudes, while in the higher parts it may fall to a depth of 3 or 4 ft., and last for a few weeks. The rocks are predominantly shale, sandstone, and conglomerates of the Bothan and Myrtle formations, which are often intruded with basic igneous rocks. A considerable area of greenstone is found in the headwaters of the Sixes river near the Rusty and Salmon mountains, while a large area of basalt occurs in the north-central part of the district. Placer mining has been done for over thirty years, in later years leading to considerable activity in quartz mining. These placer deposits contain besides gold, some platinum and iridium. The beach sands at the mouth of the river have been successfully worked for gold and platinum for a number of years past.

UTAH

OUTLOOK FOR UTAH MINING DURING 1920.—ACTIVITY IN TINTIC DISTRICT.

SALT LAKE CITY.—The close of 1919 finds unsold domestic copper in volume probably as great as at the beginning of the year, despite the heavy curtailment in

output. It is expected that this surplus will be absorbed rapidly when foreign buying begins, as the need for the metal abroad is unquestioned. It is believed among local copper mine operators that unless unforeseen factors appear, the copper producers should be operating on substantially a normal basis before the close of 1920. The lead market has shown marked improvement lately, and it is generally conceded that silver will remain at high prices and in active demand for an indefinite period. The splendid position of silver, which broke all previous records for decades in 1919, will without doubt cause active operations in all the silver camps of the State in 1920. The metal-mining industry of the State as a whole had the least profitable year since 1915. This was due to the small demand for copper and lead and the continuation of high operating costs. The total dividends paid by the metal mines of Utah to the close of 1919 were almost \$213,000,000, more than one-half of which has been distributed in the last eight years. Nearly one-half of the above total, or slightly over \$101,000,000, has been distributed by the Utah Copper Co. alone.

ALTA.—Forty feet of ore, extending for a distance of 130 ft., is now exposed in a drift to the south of No. 8 raise in the Columbus Rexall mine, according to M. R. Evans, general manager. The ore was struck during the early part of December. An average assay shows 41.4 oz. silver, 18.9% lead, and 0.25% copper. The trend of the orebody is such as to indicate that it will eventually lead to the place where mineral was found in the old work on the Kenebec claim, and if this proves to be the case, the company will have a large area of potentially productive ground.

PARK CITY.—Not for many years has there been so much development work under way as the new year finds at the Ontario, the oldest mine in the district and one of the heaviest shippers of silver ore. At present the shaft is being sunk to the 2000-ft. level, which is 500 ft. below the drain-tunnel. There are four places on the 1700-ft. level from which ore can be mined, and it is to get under these orebodies that the work is being done on the 1800-ft. and 2000-ft. levels. On account of the high price of silver, the Ontario is today shipping material which a few years ago it would have been unprofitable to move.

Following the settlement of litigation with the Silver King Coalition, the Keystone company began operations on December 26, with Andrew Hurley in charge of the property. Ore is exposed in four places where it can be mined with but little work. The company has no hoisting or pumping operations to contend with, and the ore readily can be stowed down to the tunnel-level. It is said that the average assay of the ore exposed runs from \$75 to \$90 per ton. The directorate of the Keystone company is composed of some of the prominent business men of Salt Lake City. H. G. McMillan is president.

ECREKA.—The Tintic Winchester Mining Co. has filed articles of incorporation for the purpose of engaging in a general mining business. The officers and directors are: George F. Tilson, president; William Haws, vice-president; L. N. Ellsworth, secretary and treasurer; S.

Trotter and H. B. Cole, additional directors. Most of the mines in camp closed for several days' holiday beginning with December 25. Ore shipments from this district for the five-day period ending December 25 totaled 131 cars, of which the Tintie Standard shipped 35; Chief Consolidated, 29; Dragon Consolidated, 14; Iron Blossom, 8; Eagle & Blue Bell, 8; Mammoth, 8; Colorado, 6; Centennial Eureka, 5; Grand Central, 4; Swansen, 4; Ridge and Valley, 3; Empire, 2; Gemini, 1; Alaska, 1; and Primrose, 1. The rejuvenation of the old Sunbeam property in the south end of the district has been brought about by the advance in the price of silver, and at present this mine is shipping approximately two carloads of ore per week with prospects of heavier shipments by spring. Several months ago E. R. Higgenson took over

the East Tintie Coalition installed a modern electric hoist, and is now awaiting the arrival of a compressor, which will enable the company to speed up its development work. Fortunately the formation through which the shaft is now being sunk is quite soft and fairly good progress can be made without the use of machine drills.

BEAVER. In driving east on the 470-ft. level of the Beaver Copper property in the Beaver Lake mining district, six inches of ore was encountered, averaging 6% zinc, 11% lead, and 19 oz. in silver. As this is a new part of the property that has never been explored at depth, the officials in charge of operations are highly pleased. In driving to the west on the same level, it is expected that the objective will be reached shortly. This drift will tap a vein which was opened up on the 200 ft.

POWER-PLANT OF THE UTAH COPPER CO., ON GREAT SALT LAKE. MAGNA CONCENTRATOR IN BACKGROUND.

this property on a lease agreement. The shaft has been re-timbered and tunnels on the 100 and 200-ft. levels have been cleared out. It is from these two levels that ore is being produced now. At the Iron King property in the eastern part of the district, four different headings are being driven, two on the 1000-ft. level and two on the lowest level of the new shaft, which has a depth of 1565 ft. While officials of the company say very little, the operators are encouraged with results obtained thus far. The winze in the Opohongo, which has already been sunk a distance of 75 ft. below the 1800-ft. level, in vein matter, will be continued, according to F. E. Birch, manager. In order to facilitate sinking, a small engine is now being installed near the winze. The 1800-ft. level in the Opohongo is equal to a depth of 2400 ft. in the Iron Blossom, so that the Opohongo winze is nearing a locality where an important orebody can reasonably be expected. John M. Bestelmeyer, manager of the East Tintie Coalition property, reports that at a depth of 90 ft. in the new working shaft there is now $4\frac{1}{2}$ ft. of vein matter, and as the fissures are in the lime, the officials feel highly encouraged over recent developments. A short time ago

level and which contains both sulphide and carbonate copper ore.

OPHIR.—The Ophir Metals Co. has taken over the property of the old Lion Hill company. At a meeting of the board of directors of the Ophir Metals, it was voted that the privilege extended to the stockholders of the Lion Hill Consolidated Mines Co., under date of September 15, 1919, whereby such stockholders were to be allowed to exchange their stock for certificates convertible into stock of the Ophir Metals Co. be limited to December 31, 1919. Over 50% of the old Lion Hill stockholders have assented to the plan and privilege extended to them and have made payment in full or in part of 20c. per share and have deposited their old stock with the Equitable Trust Co. of Boston.

GOLD HILL.—The Western Utah Copper Co., according to O. F. Brinton, manager, is shipping 125 tons of ore daily to the smelters, and in addition is handling 50 tons per day at its new mill recently erected to treat the low-grade ores of the district. Development work on the 700-ft. level has disclosed a vein of good milling ore for a distance of 150 ft. from which much is expected.

BRITISH COLUMBIA

SAMPLING PLANT AT PRINCE RUPERT.—VANCOUVER MANGANESE SHIPMENTS PROFITABLE.

CARIBOO. E. E. Armstrong, who located the properties on Prosperine mountain which are being developed by Robert Bryce and associates, has formed a syndicate to develop other properties in the vicinity of Barkerville. The syndicate is capitalized at \$1,000,000. Mr. Armstrong, with others, owns property through which the belts of ore that the Bryce syndicate is developing are supposed to run.

PRINCE RUPERT.—A syndicate has been formed to build a sampling works in this city, for the purpose of buying ore from small companies that do not produce enough ore to make shipments to a smelter. The ore will be sampled and assayed, and the producers will be paid full value less brokerage, smelting, and shipping charges.

HAZELTON.—The American Smelting & Refining Co. has closed a deal with the Sunrise mine, and development operations will be started early in the year. Operations at the Skeena Mining & Milling property, on Hudson Bay mountain, have been suspended pending a meeting which has been called to discuss future plans. S. A. Davis has taken an option on the Paddy Higgins property, on Driftwood creek, and will start development operations at once. The Cassiar Crown Copper property, on Grouse mountain, is developing well. A drift has been driven on the vein for 200 ft. The vein is 26 ft. wide and assays \$35 per ton. A second tunnel is being driven to cut the vein at 280 ft. The sudden thaw has caused a mud-slide in the new tunnel at the Silver Standard mine and the present tunnel has been abandoned. A new site for the tunnel has been selected, and, though it will necessitate 400 ft. additional driving, it will make a far better working tunnel.

PERMIE.—A large majority of the miners throughout district 18 have renounced the United Mine Workers of America in favor of the 'One Big Union'. The miners have accepted the 14% advance in wages, offered by the owners in conformity with the agreement between owners and employees in the United States, but they will fight any attempt to force a separation with the O. B. U. As the mine owners persistently have refused to acknowledge this union, a deadlock is likely to occur. The Crow's Nest Pass Coal Co. has increased the price of coal 34c. per ton to meet the increase in wage.

COWICHAN.—Having shipped 500 tons of manganese ore with satisfactory results, the British Columbia Manganese plant, situated on the E. & N. railway in the Cowichan district, Vancouver Island, is making arrangements for the construction of an aerial tramway. With better transportation facilities it will be possible to increase the output of the mine. The tram is expected to be in shape within two months. Meanwhile no shipments are being made because the road is in poor condition. In a letter to the owners, Guy S. Rowe, second vice-president of the Bilrowe Alloys Co., at Tacoma, expresses himself as pleased with the quality of the Vancouver

Island manganese ore. He says that this ore analyzed not lower than 48% manganese, with some cars going over 50% manganese, and that it contained no deleterious elements in sufficient quantity to interfere with the manufacture of standard 80% ferro-manganese. He hopes that the company will be in a position soon to enter into a contract to supply three cars of ore, or about 120 tons per week.

KASLO.—Word has been received of the discovery of a 5 ft. vein of high-grade silver-lead ore at the Silver Bell mine on the south fork of Kaslo creek. The vein is made up of three feet of galena and two feet of high-grade carbonate. The Silver Bell is being operated by R. F. Green and Clive Pringle, of Ottawa, under the management of W. E. Newton. The Index and Flint properties on the south fork of Kaslo creek are shipping a car of ore; the Ufca at Paddy's Peak is shipping its sixth car; while the Whitewater and other properties of the district look promising. In fact, silver-mining prospects were never brighter in this part of British Columbia.

KAMLOOPS.—Diamond-drilling on the property of the Aspen Grove Amalgamated Mines, Ltd., is making good progress. About 60 ft. per day is being bored with one shift working. Three shifts will be employed soon. In the spring, or as soon as weather conditions permit, two other drilling outfits will be started on an extensive exploration and development program.

OMINECA.—Development with encouraging results has been done on the property of the Cassiar Crown Copper Co., Grouse mountain. Some time ago a tunnel was driven which tapped the vein known as the Ruby, at a depth of 80 ft. The vein was well defined and it was drifted on for 200 ft. The value of the ore went up to \$35 per ton. More recently another tunnel has been driven to tap this same formation at a depth of 280 ft. When this second tunnel has been finished and the ore proved, it is proposed to build a new plant at a point farther down the hill, where the Ruby vein outcrops, and run a drift that will give a further depth of several hundred feet.

VICTORIA.—There are data available now indicating some changes in the mine output of the Province for 1919 as previously estimated. Contrary to earlier expectations, the output of silver will be slightly in excess of that of 1918. This is accounted by the fact that the returns from the Sullivan mine, operated by the Consolidated Mining & Smelting Co. for the latter part of the year were more than was looked for, and also by reason of the accumulated production of small shippers of the Slocan district, to which insufficient attention was paid in the compilation of estimates. Gold and lead production also will be somewhat above what was estimated, although not equaling the mark established in 1918. As to gold, the explanation lies in the speeding up of the output of the Rossland mines, also operated by the Consolidated Mining & Smelting Co. of Canada. The difference in regard to lead is due to the increased activity at the Sullivan mine and to the small shippers of the Slocan district.

ONTARIO

METALLURGICAL RESEARCH.—1919 DIVIDENDS FROM COBALT, PORCUPINE, AND KIRKLAND LAKE.

TORONTO.—Some important investigations in connection with the metallurgical industries are being promoted by the Canadian Advisory Council for Scientific and Industrial Research. A grant has been made to C. W. Drury, professor at Queens University, for an investigation to determine a suitable slag for smelting ores containing vanadium, the economic extraction of which is now difficult. Assistance is also given to Prof. Stanfield of McGill University to enable him to continue researches on the reduction of iron ores with the use of gases and the electric furnace, which have been in progress for over a

COBALT. The annual report of the Comag as shows an output of 940,267 oz. of silver, as compared with 974,264 oz. for the previous year. Combined sales of ore from the Cobalt mine and of products from the reduction plant at Thorold yielded \$3,574,156. President Leonard reported that no new discoveries of ore had been made, and that continuous operation was apparently dependent upon the capacity of the mill to work low grade ores, and re-grind and re-treat sand tailings, which might keep the mill running for three years. A large tonnage of low grade ore had been developed with occasional streaks of high grade. The surplus was \$2,103,715. The Northern Customs concentrator is developing good milling ore on the Silver Cliff property and treating about 50 tons daily at its mill. The same company has started stoping on the

MOTHER LODE MILL, SHEEP CREEK DISTRICT, NELSON MINING DIVISION, B. C.

year with encouraging results. Provision has been made by the Council for 40 bursaries, studentships, and fellowships to be awarded to qualified science graduates of Canadian universities who will train for carrying on researches in connection with the development of national resources. This is nearly twice the number provided for in 1919.

DIVIDENDS BY MINING COMPANIES.—The Northern Ontario mines during 1919 paid dividends to the total amount of \$6,600,383 in addition to \$867,430 declared payable after the first of the year. There are ten companies on the list of dividend payers. The dividends declared in 1919 by six Cobalt mines totaled \$4,999,772—three at Porcupine disbursed \$2,368,042, and the Lake Shore of Kirkland Lake paid out \$100,000. The total dividend payments from the beginning of the industry to December 31 are as follows: Cobalt, \$80,780,513; Porcupine, \$15,129,126; and Kirkland Lake, \$591,125; a grand total of \$96,500,765.

second and third levels of the property recently acquired from the Chambers-Ferland and will shortly commence taking out ore. The Temiskaming is devoting attention mainly to the development of a large tonnage of milling ore and has considerably increased its scale of operations, having 16 machines at work as compared with two in the spring.

W. E. Simpson, representing the Cassel Cyanide Co. in Canada, in discussing the question of constructing light narrow-gauge railways to the outlying mining localities of Northern Ontario, stated that in a case like that of the Gowganda silver district, where a railroad built would likely become a trunk line, a narrow-gauge line might be unsatisfactory. This belief is based upon actual experience in Western Australia, where much loss and inconvenience has been caused by difficulty of linking up lines of different gauges. This phase of the situation is being drawn to the attention of the Ontario government.

Mine operating officials in Ontario are contemplating the organization of the 'Ontario Chamber of Mines'. It is proposed to make the organization completely representative of all mining activity, with branches in each of the mining centres and with one executive at a central point. It is argued that when the executive of such an organization speaks he will carry with him the support of the majority of the mine operators. The aim is to influence legislation. It is now estimated that the shoot recently opened at the Crown Reserve will yield \$140,000 in high-grade ore, besides a considerable tonnage of mill rock. The ore-shoot proved to be a faulted section of one of the veins worked in former years. A financial statement issued last month shows the Nipissing to have a surplus of \$4,463,078.

PORCEPINE.—Work on the Dome Extension at the 600-ft. level is said to have placed in sight a large tonnage of medium-grade ore. The Dome is preparing to start cross-cutting from its property into Dome Extension territory on the 1150-ft. level where diamond-drilling has indicated large lenses of ore. The Norwoods Mining Co. has discovered by diamond-drilling a 5-ft. quartz vein which the cores show to have been penetrated at a depth of 600 ft. The vein material is impregnated with sulphides and warrants further work.

MATACHEWAN.—At the Matachewan development work has been suspended and the management has undertaken exploration on an increased scale with two additional diamond-drills.

GOWGANDA.—The Castle shaft has reached the 100-ft. level, where a station will be cut and drifting undertaken. The vein retains its width and grade. The camp buildings on the Walsh property on Miller Lake are being put in shape and a comprehensive plan of development has been adopted. The property is equipped with some mining machinery and has a shaft 200 ft. deep.

SONORA

CANARIO COPPER ACTIVITIES.—EXPORTS THROUGH AGUA PRIETA.

NACAZARI.—One of the more important discoveries in recent years in this district is the big orebody opened by the Canario Copper Co., a New Jersey corporation, on the 300-ft. level of its shaft on the Lily Segundo group, five miles south-west from Nacozari and about the same distance north-west of Pilares. James P. Harvey, president and managing director of the company, following inspection of the mine stated that the drift had proved the ore for 120 ft. with the limit not yet reached and the value increasing with the progress of the work. Assays average about four per cent copper. The find encourages Mr. Harvey's belief that the orebodies will show enrichment at depth. On the upper levels large bodies of copper ore carrying an average of 2 to 2½%, have been opened. The opening of so large a body of copper ore in this part of the district, hitherto practically unexplored at depth, is important as it indicates the value of the undeveloped ground intervening between the Lily Segundo and the great low-grade copper mines of the

Moctezuma Copper Co., at Pilares. The Lily Segundo has passed the 'prospect' stage, but Mr. Harvey advises the stockholders to continue development for at least another year, before building a concentrator. The property is a close corporation, owned by George F. Shurtleff and others. Approximately 200 men are employed at present. A good wagon road connects the Canario holdings with Nacozari, its rail shipping point. The company owns motor-trucks which are used to haul supplies at the present time.

SAN JULIAN.—Because of difficulty in securing freighters the installation of the San Julian mill has been delayed considerably, but George F. Fast, manager, is here pushing work as rapidly as possible. It is his expectation that the mill will be operating by March 1 producing molybdenum and tungsten concentrates. Mr. Fast first worked the San Julian several years ago at the time of the tungsten boom. When this metal became a drug on the market, the molybdenum became valuable on account of war time demand. A great many carloads of high-grade ore were sold to the United States during the war period. Following the War mining was stopped while a series of experiments was undertaken. This resulted in the discovery that a high-grade concentrate could be made which would find a ready market. Coarse grinding will be done in a ball-mill and the pulp sent through a K. & K. flotation machine used as a rougher, with a baby machine as a cleaner. The tailing then will be sent over tables where the heavy tungsten contained in the ore is recovered as a concentrate, which is in good demand in the United States.

MINA MEXICO.—Carl P. Haller, who will be superintendent of this property, has arrived from El Paso and assumed his duties. Sam Supplee, master mechanic, is in Moctezuma receiving and re-shipping the new machinery for the property's flotation mill. A ball machine and flotation machines will be used to treat the mine dumps which contain about 60,000 tons of material. While this is in progress, pumps will be installed to unwater the mine so that operations on the lower levels can be started. Several American mechanics are on the property and with a force of 30 Mexicans are repairing and re-arranging the concentrator machinery for the new system of ore treatment to be used.

AGUA PRIETA.—A slight increase was shown in ore exported into the United States through the port of Agua Prieta during the month of December, the total being 212 carloads with a valuation of \$1,857,800, as against 197 cars valued at \$1,655,000 during November. Tonnage is smaller in December being 9099 as against 9648. The increase in value was effected through heavy shipment of concentrates. Ore shipment was somewhat hindered by the increased shipment of wood from Cos and vicinity to meet the demand occasioned by the coal shortage. The mines shipping were: Nacozari, 7820 tons; El Tigre, 540 tons; Estrella, 485 tons; Las Chispas, 41 tons; San Pablo, 38 tons; San Nicholas, 41 tons; San Luis, 81 tons; La Roy, 16 tons; San Jose, 18 tons; Santa Rita, 19 tons; Progreso, 300 lb. gold-silver precipitates.

ARIZONA

Globe.—John F. Barry, secretary of the Superior & Boston Copper Co., states: "Since striking the foot-wall vein last month on the 400-ft. level, we have shipped, from development work alone, eight carloads of ore averaging \$72 per ton, and netting a total, after deducting smelting charges, of approximately \$21,000. The north cross-cut on the 1200-ft. level, east of the Quo Vadis fault, has cut an apparently barren vein, presumably the Great Eastern. The exploration work for the Old Dominion vein is making good progress."

Jerome.—The holdings of S. S. Ballard, north-west of the old Haynes properties, embracing an area of 80 acres, has been sold to the United Verde Consolidated Copper Co. for \$60,000. This property has been under development at intervals for many years.

Kingman.—Financing of the White Star Mining Co. is under way and development of its silver property is to be commenced immediately. Machinery consisting of hoist, compressor, and other operating equipment is on the way to the property.—The famous Lagoon copper mine in the Wallapai Indian reservation which was opened to prospectors on November 1, has been located by C. H. Dunning of Prescott and is now in operation. This mine is said to be showing well.—The McCracken Silver-Lead Co. recently shipped a car of 50 tons of lead-silver ore.—The cross-cut on the 300-ft. level of the United American has not yet penetrated the hanging wall of the lode although a large quartz vein has been passed through. It is the intention of the company to sink immediately to the 500-ft. level.

Mayer.—The steel head-frame of the Arizona Binghampton in the Mayer district is half completed and re-timbering of the shaft has commenced, the working force being increased to 80 men for this purpose.—The Big Ledge Mining Co. is getting the Mayer smelter into shape to make a test run of at least 75 tons of gold-bearing ore from the Henrietta mine.—The Yaba Copper Co. has taken over the old Carroll property which has been owned by Carroll for twenty years. A shaft 250 ft. deep has developed silver ore.

Miami.—Churn-drill operations have been started by the Porphyry Consolidated Copper Co. and a diamond-drill is being installed on the 650-ft. level.—Construction work on the new mill of the Iron Cap Copper Co. is progressing favorably. The foundations and flooring are practically completed. The frame work of the mill is partly up and the grading of the narrow-gauge railroad from the mine to the mill is two-thirds completed. Drifting is being done in the new orebody recently opened on the 1000-ft. level.

CALIFORNIA

Colfax.—Dewatering of the Rising Sun mine is proceeding rapidly and the management expects to be able to develop from the lower levels soon. The pump has a capacity of 400 gal. per minute. All equipment is electrically operated.

Murphys.—Drifting on the vein recently uncovered in the lower tunnel of the Tanner quartz property is progressing with a larger working crew. The tunnel is 1300 ft. long and taps the vein 300 ft. below the old one. The vein is

three feet wide with a good grade of ore. C. W. Canfield is superintendent.

Forbestown. San Francisco people have taken an option on the Midas gold-quartz mine on the Feather river, according to a report reaching here. The Midas has been undergoing development for several years and some excellent mill ore is exposed. Fred Bachman is owner.

Needles.—The deposit of rich gold ore found recently in the Chinchuevis mountains by Simmons and Widrikan is attracting interest and prospectors are locating many claims. The original discovery is being prospected and is said to be showing well. The selected ore is slated to assay \$16,000 per ton, with some shipping ore exposed.

IDAHO

Coeur d'Alene.—The Polaris and Yankee Boy mining companies are planning a consolidation which is said to have already received the approval of controlling interests. Extensive development plans are to be undertaken by the consolidated company. They include a tunnel 2000 ft. long from the workings of the Yankee Boy into the Polaris ground to open the latter to a depth of 1500 ft. The Yankee Boy has a good power-plant.—Extensive development work has been commenced by the Lombardy Mining Co. at Kellogg. A cross-cut will be run 330 ft. on the tunnel-level in a north-west direction to cut the orebodies shown above. This will be followed by another cross-cut 200 ft. lower, which is expected to block out some ore.

E. C. Tousley, of Spokane, has taken a two-year bond on most of the stock of the Yankee Girl Mining Co., the price to be paid being \$60,000. The property consists of 10 claims lying south of the Polaris and Yankee Girl holdings and adjoining them. Mr. Tousley must commence work developing the property before April 12.

The East Caledonia Mining Co., the owner of property adjoining the Caledonia at Wardner, expects to resume operations soon after January 1.

MONTANA

Anaconda.—Virtually all departments at the Anaconda company's Washoe smelter, made idle by the recent coal strike, had resumed operations by January 1. This means the smelter is now being worked at 60% of its maximum capacity. The mines at Butte had been in operation since December 22.

Boulder.—The officers of the Liverpool Silver Mines Co., which is re-opening the Liverpool, one of the famous old producers in Jefferson county, report the development for a distance of 600 ft., of a 30-in. vein assaying from 40 to 90 oz. in silver. The work was done on the 750-ft. level. The district is experiencing a mild 'boom'.

MISSOURI

Joplin.—The estimated output for the district during 1919 follows: Blende, 827,651,690 lb., value \$18,128,384; calamine, 20,353,040 lb., value \$289,598; lead, 139,049,470 lb., value \$4,417,329; total value for year, \$22,835,311.

The Underwriters No. 4 mill, a new 400-ton plant recently put in operation, has been working satisfactorily, coming

up to the expectations of its owners and builders. F. N. Bendelari, general manager; Fred Carpenter, superintendent; I. L. Box, constructing engineer; and Ed. Gill, foreman of construction, are satisfied with the new plant.—The Tri-State Section, American Zinc Institute, substituted a turkey dinner for the transaction of business at the meeting held on December 23 at Picher.

NEVADA

Austin. The International Victory company announces important ore discoveries in the Yankee Blade, near Austin, and in the claims operated at Birch Creek. In the Yankee Blade an 8-ft. vein of milling ore is exposed containing some ruby silver. J. H. Schwefle is manager. —Shipping ore has been uncovered in the Diana shaft workings of the Austin Manhattan group, coming from the Morgan & Muncey vein, which is 18 in. wide.—The Cahill Lode and Bradley Divide companies, operating at Birch Creek, have discontinued sinking until heavier equipment can be put in.

Ely.—Minerals Separation North American Corporation has made another move in its litigation against Nevada Consolidated Copper Co. by filing a bill of interrogatories in the Federal Court at Portland, Maine. Armed with replies to their questions the lawyers for the plaintiff in the suit will not be obliged to ask so many details when the case comes to trial. Nevada Consolidated has been asked to describe its process of flotation, giving details as to quality and quantities of oil used. It has also been requested to show earnings of equipment and process and to supply flow-sheets. Minerals Separation asks if Nevada Consolidated uses air in its flotation process and if so how it is introduced.

Virginia City.—Importation of two carloads of provisions by the mining companies and sale at cost has reduced materially living expenses here.

Obituary

Further news has been received concerning the details of the drowning of **Reuben Edward Smith**, an American mining engineer, in Siberia. The accident was caused by the overturning of a boat in the rapids of the upper Ulya river, on the west coast of the Okhotsk Sea, on August 29, last year. Smith was a man in the prime of life, about 45 years of age, and had resided at Vladivostok and in East Siberia for a period of fifteen years. Born in the placer-fields of California, he was essentially a practical engineer of sound judgment and accomplishment. Receiving early training with his father in the construction of placer-mining plants in California and Colorado, he at the same time prepared himself in the theory of mechanical and electrical engineering. He proceeded to Vladivostok, where for several years he was in charge of coal-mining operations in the Suchan district. He was engaged extensively in the examination of gold-placer deposits in Korea and Siberia, and for the three years from 1913-16 was in charge of important work in improving gold-mining methods at the mines of the Lenskoe company in western Siberia. Upon the entry of the United States into the War he was engaged in the service of the Consular, Military Intelligence, and War Trade departments at various points in Siberia, and performed most valuable work for the Government. He had only taken up private work again in the summer of 1919 in charge of exploration work in the Okhotsk goldfield. He leaves a wife and two children. Smith had an invaluable knowledge of the Russian language and character, and perhaps the most useful knowledge of any foreign engineer of the psychology of the East Siberian laborer. As a man he was most highly esteemed by all who knew him, and his untimely death is lamented by a wide circle of friends at Vladivostok.

C. W. P.

Personal

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

R. G. Hall has returned to Burma.

J. Coggin Brown is in London on leave.

Herbert Hoover has returned to Washington.

H. Foster Bain writes from Rangoon, Burma.

C. H. Munro is at Ipoh, Federated Malay States.

L. J. Mayries has returned to India from London.

R. L. Douglass, of Fallon, Nevada, is at the Bellevue hotel.

Hunter Mann has arrived in San Francisco from Hankow, China.

Frank L. Hess and **Frederic J. Siebert** are on their way to Bolivia.

C. B. Lakenan has been at Los Angeles and San Francisco recently.

H. R. Wagner, of the A. S. & R. Co., has returned from New York to Berkeley.

E. F. Yates, formerly of the Miami Copper Co., is now city engineer of Globe, Arizona.

Reiji Kanda sailed by the "Korea" on January 7, returning to Japan from British Columbia.

Vernon S. Rood, manager for the Utah Apex Mining Co., at Bingham, is in San Francisco.

John Morgau has become a director of the Colombian Mining & Exploration Co., London.

F. P. Mennell is engaged in geologic investigation at the Rhodesia Broken Hill mine, in Rhodesia.

M. B. Cutter, of Minneapolis, and **Clyde Heller**, of Philadelphia, were in San Francisco this week.

Dudley Inskip is returning to London from Burma, where he has been in the Mawchi tin mine.

W. L. Brown has returned to London, and is in charge of the operations for relief in eastern Europe.

Richard A. Parker is at Duluth. He is visiting the iron and copper regions of Minnesota and Michigan.

A. J. Robin, formerly of the Mazapil Copper Co., is now with the A. S. & R. Co., at Aguascalientes, Mexico.

David Wilkinson succeeds **C. D. Leslie** as consulting engineer to the Consolidated Gold Fields of South Africa.

Stanly A. Easton, manager for the Bunker Hill & Sullivan Mining Co., is at the Claremont hotel, Berkeley, on a short visit.

M. Suzuki, manager of the Hikoshima zinc smelter, Japan, has been in Utah recently, visiting metallurgical plants and mines.

Frank H. Probert, dean of the Mining Department of the University of California, is in Arizona. He returns on January 11.

J. A. L. Gallard has resigned as mining editor of the "Financial Times", in London, a position that he has held since 1902.

H. W. Darling, field engineer for the Crown Reserve Mining Co. of Montreal, passed through San Francisco last week on his way to Northern Ontario.

Robert H. Richards has joined in business with **Charles E. Locke**; the office of the new firm of consulting engineers will be at Cambridge, Massachusetts.

A. H. Heller has been appointed general superintendent for the Afterthought Copper Co., at Ingot, California, in succession to **D. C. Smith**, who has resigned.

William Huff Wagner has resigned his position as geologist and chief engineer for the North Butte Mining Co. to join the technical staff of the Income Tax Bureau on Mines, at Washington.

EASTERN METAL MARKET

(By wire from New York)

January 6—Copper is quiet and strong. Lead is active and higher. Zinc is feverish and soaring.

SILVER

Below are given official or ticker quotations in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

In the letter which the Federal Reserve Board has sent to chairmen of Federal Reserve banks advising them of the peculiar situation arising from the practice of basing interest rates on interior bank balances allowed by members of New York Clearing House, in accordance with 90-day discount rate at Federal Reserve banks, and calling for a general meeting of representative bankers from all parts of the country in Washington for discussing the matter and possibly bringing about a modification of existing regulation, the Reserve Board has rather misrepresented the plan in operation among local clearing-house banks, according to some bankers. Discussing the marking up of interest rates on deposits early last year, the Board, in its letter said: "Finally the clearing-house banks of New York agreed to fix a rate of 2½% on bank balances payable on demand, with proviso that the interest rate would be automatically advanced or reduced ½ of 1% with each advance or decline of ½ of 1% in the 90-day rate at the Federal Reserve Bank of New York. This rate is now 1½%, and should it be advanced at any time to 2%, the rate of interest paid by New York banks for all of town bank balances would advance automatically to 2½%, and a 3½% rate at the New York bank would advance the interest on bank balances automatically to 3%, and so on."

To certain financiers this conveys the impression that there is no limit to the amount of interest the local banks may pay for deposits and that the higher the Federal Reserve Bank raises its discount rates, the higher will be the interest paid on deposits in New York. But local banks are restricted to pay not more than 3% on demand deposits. As a matter of fact the clearing-house banks did not fix the rate at 2½% on that occasion. The rate became 2½% by reason of amendment to the constitution effective October 1, 1918. It was stipulated that no member of the Clearing House Association or others clearing through members should pay on any check, balance or deposit payable on demand or within 30 days for account of any banking institution in the United States or Canada "interest at a rate in excess of 1% per annum when the then 90-day discount rate for commercial paper at the Federal Reserve Bank of New York is 1% or less, or any additional rate of 1% for every ½ of 1% that such discount rate of the Federal Reserve Bank shall exceed 2%, except that the maximum rate paid or agreed to be paid on any such credit balance or certificate of deposit shall not in any case be higher than 3% per annum."

It is believed that Federal Reserve banks will soon raise discount rates on commercial paper. Under the last few months' discount rates on paper secured by Government war obligations have been raised twice, and these increases tended to reduce borrowings on this class of collateral. But while this was taking place a considerable expansion was going on in commercial borrowing at central institutions. For this reason, the next step to be taken by reserve authorities is expected to be an increase in discount rates on so-called "business paper" or bills secured by collateral other than United States war obligations.

This applies to commercial paper, bank acceptances, and trade acceptances. It is this class of paper in which unquestionably a large part of the commodity speculation is tied up. It has been pointed out by the Federal Reserve Board on several occasions that the Wall Street stock market was not solely responsible for undue speculation that has been going on, but that similar activity prevailed in all commodities the country over.

Foreign exchange quotations on January 6 are as follows:

Sterling, dollars.....	Cable.....	3.79 1/2
France, cents.....	Demand.....	3.78 1/2
India, cents.....	Cable.....	9.25
Japan, cents.....	Demand.....	7.54
Marks, cents.....	Demand.....	2.03

Eastern Metal Market

New York, December 31.

All the markets show decided strength and most of them are active and higher as the old year draws to an end. Heavier demand for copper is reflected in advancing prices.

Quietness pervades the tin market but prices for spot are higher.

Supplies of lead are not equal to the heavy demand and higher values prevail.

Zinc quotations are considerably higher on better domestic, and particularly foreign, demand.

Antimony is unchanged and quiet.

IRON AND STEEL

There is more activity in the iron and steel markets at the opening of the year than is commonly the case, most of the mills carrying over into 1920 such large tonnages in certain lines, as to preclude new business for many weeks.

According to the annual review of "The Iron Age" only nine open-hearth steel furnaces were completed in 1919 capable of producing 625,000 tons of ingots per year. Only 22 furnaces are under construction with an annual capacity of 875,000 tons. Not since 1911 have so few new furnaces been under construction. In the four years beginning January 1, 1915, no less than 14,000,000 tons was added to the country's open-hearth steel capacity by new construction. Though for several years pig-iron capacity has not kept pace with the increase in steel plants only two blast-furnaces were completed in 1919 and only four, with a total annual capacity of 700,000 tons, are now under construction. Negotiations over rail purchases involve probably 1,000,000 tons. The shortage in semi-finished steel has been emphasized by the shipment of sheet bars from the Chicago district and from Duluth to the Pittsburgh district.

The Lake Superior iron-ore trade looks for an advance in prices in 1920.

COPPER

Sellers report a much more active demand from both domestic and foreign consumers. Buying in December has been good and it is expected that in January it will be still better. The steadier foreign exchange market has also been a stabilizing factor as well as an incentive to better buying. Consumers are realizing that the 18c. price early in December was a low level. Brass makers are more interested and British and Japanese buying, as well as some from Scandinavian countries, is prominent. Electrolytic copper is quoted at from 19.25 to 19.50c., New York, for early delivery, with only one or two small sources from which it can be obtained at 19c. Lake copper is quiet and strong at 19.50c., New York, for early delivery.

TIN

The week has been very quiet and there has been little buying. The market has been dull and uninteresting. Prices for spot tin advanced almost daily in sympathy with a firmer trend in the value of the pound sterling and because also of a rapidly advancing market in London. The London market is largely a speculative one and apparently under close control. It advanced on Monday, December 27, £7 15s., or to £337 10s. per ton. Yesterday spot Straits was quoted at 59.25c., New York, an advance of almost 4c. per lb. in the week. American buyers are holding off because of present conditions although a little business has been done. Future shipments from the East are quoted nominal at around 59.50c., with some sellers asking 60c. Tin arrivals thus far this month have been 4953 tons, of which 1190 tons came in at Pacific ports. The quantity afloat is 3259 tons.

LEAD

The situation in the lead market can be completely described by the statement that supplies are not equal to demand. As a result consumers are becoming frightened and are bidding up the market on themselves. The outside market has been constantly in advance of that of the 'leading interest' which on December 26 advanced its quotation for the fourteenth time this year, or from 7.15c. to 7.30c., New York, or 6.90c. to 7.25c., St. Louis—an advance of 35 points. The outside market continues to keep ahead and today is quoted at 7.75c., New York, or 7.50c., St. Louis, with the tendency upward. The outside interests determine the price levels at present.

ZINC

The market continues to grow stronger and prices are considerably higher than for some weeks. Demand and inquiry from domestic consumers has not only expanded in the last few days, but foreign buying has taken another spurt. Part of the latter is due to better exchange, but the British buying is also accounted for by the fact that smelters over there can buy in the United States cheaper than they can produce. One estimate here is to the effect that the British cost is at least 11c. per lb. The technical position of the market is also very strong, as producers are not anxious to sell because they are comfortably sold up for the immediate future. As a result of the foregoing conditions, prime Western has advanced to 9c., St. Louis, or 9.35c., New York, for January delivery.

ANTIMONY

The market is quiet and quotations for wholesale lots for early delivery are unchanged at 9.62½c., New York, duty paid.

ALUMINUM

For wholesale lots of virgin metal, 98 to 99% pure, quotations are nominal at 32 to 33c., New York, for early delivery.

ORES

Tungsten: The market is quiet with quotations nominal at \$7 to \$15 per unit, depending on the grade of the ore and whether Chinese, Bolivian, or American. Very little activity is expected for some weeks. Quotations for ferro-tungsten are nominal at \$1 to \$1.10 per lb. of contained tungsten, with no open business reported.

Molybdenum: Quotations continue nominal in a quiet market at 75c. per lb. of MoS₃ in regular concentrates.

Manganese: Some Cuban and South American ore is reported sold at 55c. per unit, but this has not been confirmed. It is stated that American producers of ferro-manganese, outside of the 'leading interest', are short of ore and are willing to pay 60c. per unit.

Manganese-Iron Alloys: Ferro-manganese is quite scarce and higher. Some regard the situation as serious. Practically no American or British alloy is now available for the first half of 1920. Sales of 100 to 500 tons of domestic alloy have been made in the last week at \$130, delivered, about 2200 tons of British alloy has sold at \$120 and \$125, seaboard. Spiegeleisen is active and strong at \$40 to \$45, furnace, and a sale of 2500 tons for export is reported.

The price of Gulf Coast crude petroleum has recently been increased from \$1.25 to \$1.50, and it is said the price of Mexican crude at Gulf Coast ports will probably be advanced to \$1.25 per barrel. Fuel-oil consumers are speculating on the effect of these advances on the general market.

Book Reviews

Technical Methods of Ore Analysis. Eighth edition. By Albert H. Lowe. Pp. 378, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.25.

This standard work on practical laboratory methods has again been revised and enlarged. The notable additions relate to molybdenum, potassium, tungsten, and uranium and include revised methods, newly developed since the last edition appeared. These are found in the appendix. When the next edition appears we should like to see a more thorough revision, with the new material embodied in the text instead of in the appendix, and some of the less preferred schemes of analysis deleted. For the student, too many alternative plans are confusing, and especially where slight modifications have been found desirable would condensation and elimination prove advantageous. As a reliable guide to the analytical chemist the book is still valuable.

Analysis of Minerals and Ores of the Rarer Elements. By W. R. Schoeller and A. R. Powell. Pp. 234, ill., index. Charles Griffin & Co., Ltd. J. B. Lippincott Co., Philadelphia. For sale by 'Mining and Scientific Press'. Price, \$5.

This book is avowedly for analytical chemists, metallurgists, and advanced students, and to such it should be invaluable. Each of the rare elements is treated under some or all of the following heads: Minerals, Properties and Compounds, Quantitative Separation, Estimation, Detection in Ores, Determination in Ores, Impurities in Ores, Complete Analysis of Ores and Technical Methods. The book is in a way a pioneer, in that it has systematically treated the complete analysis of rare-element minerals. Some of the material is original; much is compiled from other literature. The authors welcome thorough investigation of their methods by analytical chemists, and hope to bring about adequate discussion of comparatively new work. A feature of the book is the presentation in tabular form of appropriate schemes for making a complete analysis of the common compounds of these elements. This economizes space and likewise makes the book more useful. Practically every element not given adequate treatment in the older textbooks is included in the present volume, which should be valuable to those concerned with analyses of this character.

The Petroleum Handbook. By Stephen O. Andros. Pp. 206, ill. The Shaw Publishing Co., Chicago. For sale by 'Mining and Scientific Press'. Price, \$2.

This purports to be 'a condensed book of reference on subjects pertaining to the petroleum industry', and the preface also states that little original matter is given. This latter, at least, appears to be true. While compilations are often valuable, this one apparently has been made by someone with relatively little first-hand knowledge. The result is that while the material is derived from authoritative sources and the facts given are correct, nevertheless, they are arranged in such a manner that the layman might easily get a number of wrong impressions regarding the industry. On the other hand, the treatment of any particular subject is necessarily so brief that the book will be of small value to the petroleum engineer or operator, since he can find but little that he does not already have at his fingers' ends without looking it up. The attempted scope of the book may be judged from the chapter-headings, which are: Origin, Accumulation, and Occurrence; Exploration and Drilling; Methods of Petroleum Refining; Natural Gas and Its Products; Shale-Oil Industry; Marketing of Petroleum Products; Gasoline Specifications; Inspection Laws, and Marketing Prices; Economic Utilization of Petroleum.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

NEW OIL-IMMERSED SWITCH

Magnetically operated main-line switches on alternating current light and power circuits are at times slow and unreliable in closing when a solenoid and plunger must be depended upon for their operation. If the plunger is slightly out of adjustment, its movement becomes jerky and noisy.

Fig. 1. New C-H Oil-Immersed Magnetic Contactor Operated by a Clapper Type Magnet and Armature, Which Increases Reliability of Operation Over the Solenoid and Plunger Type.

its sealing pull is diminished, and it does not seat properly.

The Cutler-Hammer Mfg. Co., of Milwaukee, has developed a new oil-immersed magnetic contactor, operated by a clapper-type magnet, which makes possible a more rigid mechanical structure and greater reliability in operation than

Fig. 2. Same as Fig. 1, but with Oil-Tank Removed, Showing Contacts and Arcing Shields.

is obtained in contactors of the solenoid and plunger type. This contactor has a capacity of 100 amperes at 2200 volts, and is particularly desirable as a main-line switch for an automatic 2200-volt motor starter, or for the remote control of any 2200-volt light or power circuit. It is built with three

poles, unless used with an auto-transformer starter when five poles are provided.

The frame of the contactor, which is of heavy sheet iron, is arranged for wall or switchboard mounting, and carries two cast-iron supports with two insulated shafts carrying the contacts. Copper-leaf brush contacts are saved from all wear due to breaking the circuit because auxiliary arcing contacts are provided for this purpose. Leads from the contacts connect with suitable terminals extending through high-tension insulators mounted on the top of the frame. The armature is firmly pivoted to the frame, and is connected by a rod to an arm of the shaft carrying the moving contacts. The attraction of the armature against the face of the magnet rotates the shaft and closes the switch, which is normally held open by the weight of the moving parts.

A flood head of oil is maintained over the contacts by providing a sheet-metal tank of ample capacity, and as the contacts are situated above the operating shaft, they are away from any sediment which might accumulate in the bottom of the tank. The arc is broken at the contacts in a horizontal direction and therefore rises to the point of rupture without burning other parts. Transite shields prevent arcing across adjacent poles.

COMMERCIAL PARAGRAPHS

G. B. Livingood, who for the past two years has been sales engineer, has been appointed assistant manager of the mining and crushing department of the Traylor Engineering & Manufacturing Company.

C. F. Braun & Co. announce that they have secured for their executive and engineering offices the entire tenth floor of the Atlas building, 604 Mission street. This will bring them into closer touch with their factory. The private exchange Douglas 1404 connecting all departments remains unchanged.

J. George Leyner announces that he has resigned as president of the J. Geo. Leyner Engineering Works Co., of Littleton, Colorado, in order to be able to devote all of his time to the Leyner Tractor & Manufacturing Co., organized for the manufacture and sale of the Linapade tractor, recently developed by him. The company's office will be at 212 Tramway Bldg., Denver, Colorado.

Revised and enlarged Bulletin No. 112-B entitled 'Condensers, Pumps, Cooling Towers, Etc.' has just been published by the Wheeler Condenser & Engineering Co., Carteret, New Jersey. This bulletin illustrates the latest developments in condenser practice, and shows, among others, a surface condenser containing 50,000 sq. ft. of surface. It illustrates and describes surface condensers, jet condensers, barometric condensers, the Wheeler-Edwards air pump, the Wheeler rotative dry vacuum pump, the Wheeler turbo-air pump, the patented Wheeler steam jet air pump, Wheeler centrifugal pumps for all services, jet condensers, barometric condensers, natural and forced draft cooling towers, feed-water heaters, and Wheeler evaporators and dryers. A free copy of this bulletin will be sent to responsible persons upon mentioning this publication.

THE annual meeting of the Institute will be held in New York on February 16 and the three following days. The papers prepared for discussion will deal chiefly with the oil industry. Mr. E. P. Mathewson is chairman of the committee on arrangements.

WE have received copies of two speeches delivered by Mr. Miles Poindexter in the Senate. These have been re-printed from the 'Congressional Record' and are mailed free as a matter of senatorial privilege. The senator from Washington is a candidate for the Presidency; he would show better taste if he desisted from advancing his candidacy at the public expense.

PEACE has been ratified, but it is a lame peace, because the United States is not a signatory. On January 16 the League of Nations comes into being, but not for us; we shall have National Prohibition instead the day after. The Armistice continues in force between the United States and Germany; therefore business with that country, and her allies, remains under restrictions.

OUR esteemed British contemporary, 'The Mining Magazine', in its enthusiastic appreciation of Mr. Sulman's treatise on flotation, says that "in America, particularly, the [flotation] processes were practically ignored. Many eminent authorities there looked askance at the English inventors, and regarded them as charlatans on the level of gold-brick merchants and bunco-steerers". This is a weird exaggeration. The application of flotation to sundry sulphide ores of copper was developed in the United States after Mr. Sulman and his associates in London had stated that the process could not be applied successfully to them. More has been done in the United States during the last five years to develop and extend flotation than anywhere else, although we are aware that the earlier development of the process is to be credited to the technicians of Broken Hill. No; we do not regard the English "inventors" as "gold-brick merchants and bunco-steerers", nor do we regard them as philanthropists and Sunday-school teachers; indeed, our ideas concerning them have been expressed quite frankly several times in these columns; what St. Peter will do to them when they knock at the pearly gates, we would not venture to forecast. This much, however, we will say, after reading Mr. Sulman's treatise for the purpose of revision before printing it in our paper, namely, that Mr. Sulman writes with the care-

fulness and the consequent clarity that marks the true scientific man, and we would be happy if only more technicians would use an instrument of precision, the English language, with similar care and skill.

HIGH COST is again to the fore in the proposal to increase the annual dues paid by members of the Institute. They have been asked to vote in favor of an increase to \$15 per annum, but as this change cannot become effective for a year, they are requested to pay \$3 extra for the volumes of Transactions issued during 1920. We have not referred to this matter until the voting was done, not caring to interfere, but we do desire to record our opinion that the Institute publishes too much stuff and that it needs more editing, partly to improve the text and partly to abbreviate it. Most of us in the West throw the papers on iron and steel into the waste-paper basket as soon as they reach us; of the mass of material published in the bulletins and the bound volumes, not more than an eighth interests any one member. Here is a lamentable waste, particularly in these days when printing, paper, and postage are increasing continually. Like most engineering societies, the Institute runs to quantity rather than quality, and tends to expend its energies in disregard of the inevitable cost; in short, the Institute publishes too much and may find it necessary before long to raise the dues again. It should meet its increased cost by diminishing the mass and improving the matter of its publications.

SOME of our readers have asked us to state the facts regarding the coinage of silver and the re-melting of coins into bullion. A newly minted dollar weighs 412.5 grains; it contains 371.25 grains of silver and 41.25 grains of copper. Subsidiary coins weigh less than their nominal fraction of a dollar, although the composition of all silver coins is the same. One troy ounce is equivalent to 480 grains, so that a silver dollar actually contains 0.7755 ounces of silver; or, stated otherwise, the market price of silver must be \$1.2926 per ounce if the silver in a dollar coin is to be worth \$1. Obviously then, silver dollars have been worth more as bullion than as coins, for the quotation for silver has averaged \$1.3356 for as much as a week. The Government will purchase silver bullion in any amount, paying for it the price quoted in New York on the day preceding that on which it is deposited at the Mint. If, however, the quotation is a fractional part of a cent, this fraction is dropped in making a set-

tlement; and charges are also made for melting, parting, and assaying the bullion purchased. These charges are not fixed, but depend upon the amount and kind of base metal in the bullion; for instance, the 'finer' the bar, the smaller will be the charges. The only requirement is that at least 200 parts in 1000 are precious metal and that the net value is not less than \$50. While it is a crime to mutilate a coin and then put it into circulation, there is no law prohibiting the melting of coins into bullion. The fact is that millions of silver dollars have lately been converted into bullion and shipped through San Francisco to the Orient, and a great many more are being melted by small 'dealers' who realize a profit by selling directly to the various mints and Government assay-offices in the United States. The Government must hold in the Treasury department in Washington enough dollars to redeem the outstanding silver certificates, but this number is rapidly diminishing as the certificates go out of circulation. The only thing that limits the number of silver dollars melted by those in the business is their ability to obtain them. The mints have not coined dollars for some time and the probable result will be gradually to eliminate the silver dollar from circulation. Not until silver reaches approximately \$1.39 per ounce will it be profitable to melt half-dollar coins, but should this price be exceeded considerably we may look for some depletion in the stock of subsidiary coins.

NOT long ago we gave some facts concerning the Premier mine, in British Columbia, 16 miles from the head of the Portland Canal. We can state authoritatively that a fifth interest was bought by Mr. Minor C. Keith, of the United Fruit Company; and a fifth by the Guggenheim Brothers, who also have an option on another fifth. The prices paid have not been divulged and the figures published are mere guesses. Mr. R. K. Neill opened up the orebody in 1918 under an option from Bush, the locator, for \$100,000, which has been paid out of ore-sales. To illustrate the richness of the ore, we can say that 286 tons brought a return of \$96,000, of which 40% in value was gold and 60% silver, at \$1 per ounce. At one time a face of ore 7 feet high and 6 feet wide averaged \$1000 per ton. The story of the discovery as previously recorded is approximately correct. Mr. Neill found an adit-level 225 feet below the surface and 252 feet long that had been driven by the previous optionees, representing Mr. William B. Thompson, who dropped the venture on the advice of Mr. Henry Krumb, on whom, not Mr. H. R. Plate, devolved the duty of deciding whether to proceed with the venture. This level started in \$6 to \$7 rock and ran in such low-grade material for about 60 feet, gradually sidling leftward into the softer country-rock, a quartz-porphry, until it was entirely away from the lode, which is paralleled for 192 feet. At the end it just touched the lode again, there being a little showing of ore in the right top corner of the face, which assayed only 51 cents per ton. Mr. Neill saw this edge of ore and took a grab-sample, which assayed \$8 per ton. He ran a cross-cut and within

four feet penetrated \$300 ore. The cross-cut was continued for 78 feet farther, and the whole 82 feet averaged \$57 per ton. The silver is in the form of argentite, proustite, and stephanite, or, as a miner would say, silver glance, ruby, and brittle silver. The ore presents no metallurgical difficulty. At present the first-class is being sacked and shipped to the smelter at Tacoma, but later the output of the mine will be subjected to flotation and cyanidation on the spot. A new adit is being driven 250 feet deeper than the prospect-tunnel and is expected to reach the orebody in April.

THERE was a time when the Tanganyika Concessions was regarded as a menace to the copper market. That was ten years ago, when hope had not been disciplined by experience. As we read the account of the recent annual meeting, it seemed as if the last five or six years had never been, for again the invincible optimism of Mr. Robert Williams and his backers shone brightly from the printed pages. Mr. Tyndale White presided and Mr. Charles Rowsell seconded the motion. The same actors; the same play. Nor do we say this in a spirit of satire, for the story of the Tanganyika Concessions is a fine example of Anglo-Celtic initiative and persistence; it exemplifies the adventurous spirit that is the very essence of mining. Mr. Robert Williams we know, and we admire greatly his indomitable energy and his keen sagacity. The shareholders are still backing him to the limit, and have allotted 200,000 shares to him in order to ensure his continued co-operation. In 1919 the Union Minière, the parent Belgian company, made a profit of £700,000. The output of copper last year was 22,000 long tons, but it would have been 40,000 if strikes and other difficulties had not interfered. It is expected to produce 40,000 tons this year. That would be a little less copper than the Utah Copper Company is producing annually. Mr. A. E. Wheeler, formerly of Montana, is consulting engineer to the company. We wish him and Mr. Williams every success in 1920.

REFERRING to deep mining on the Kolar goldfield, in India, and more particularly the impoverishment of the celebrated Mysore mine, we note the statements made at the annual meeting of the Mysore Gold Mining Company, as reported in the 'Financial Times'. It was stated by the chairman, Lord Glenconner, that "a mine that has produced £20,000,000 worth of gold and is still carrying in depth the reef [or vein] which has given such results may be looked upon as offering an unusually good prospect of renewed success". This was greeted with "Hear, hear"; but we venture to suggest that when a mine is 4000 feet deep and is poor in bottom, the prospect is gloomy. The fact that it has yielded millions in gold simply indicates that there are just that many millions fewer to extract. The Right Honorable Chairman added that he and his co-directors were "strengthened to that opinion by the fact that at the Oregum mine, which is deeper than our own, valuable ore-ground is again being opened up at the deepest points". This is mis-

leading—unintentionally, of course. The ore-shoots of the Kolar goldfield pitch northward at a strong angle, so that any shoot that the Mysore might intercept at, say, 4500 or 5000 feet in vertical depth, would be cut in the Ooregum at between 6000 and 6500 feet, whereas the Ooregum is, we believe, barely 5000 feet deep vertically. Why mention the Ooregum and not the Champion Reef, which comes between the Mysore and the Ooregum? The best evidence concerning the probability of finding new ore-bearing ground in the Mysore should be obtainable from its adjoining neighbor northward, in which any deeper ore-shoots might have been intercepted, because the Champion Reef is the deeper of the two. The fact is that this mine also is sick in the bottom. This vital question of impoverishment in depth is being tackled in an absurdly unscientific way, in disregard of local evidence as well as of world-wide experience. What the Mysore shareholders need is a report by an independent engineer thoroughly versed in the vicissitudes of gold mining. It looks to us as if the patient were extremely ill, and the kindly old family physician were so unwilling to hurt the feelings of the relatives as to object to calling in the aid of a specialist. Moreover, the relatives are so fond of the invalid that they hate the idea of a cold-blooded verdict from an unsympathetic outsider.

SMOULDERING underground fires cause much trouble in metal-mining, entailing difficulties in ventilation, expense for bulkheading, and in many instances the loss of valuable ore. Danger is a minor factor, as methods of fire-fighting have been so perfected that, when the fire has once been controlled, operations in the remainder of the mine usually can continue undisturbed. In exceptional cases, stoping may even be done under forced ventilation within the burning area. Some fires have been smouldering for twenty or thirty years, resisting the best effort to extinguish them. The reason, of course, is found in the rock-fractures that are present in every ore-bearing zone; such crevices admit air sufficient to support combustion, the area usually being so large that concrete bulkheads can only control, not extinguish, the fire. Heavy timbering, such as that in the Butte mines, is always a possible source of danger; but by far the most difficult fires to control are those in sulphide ore. There seems to be good evidence that, when the proportion of sulphur is sufficiently high, fire can start from spontaneous combustion, assisted probably by the heat generated from rock-movement. Such is that in the United Verde mine at Jerome, which has been burning since 1897. Most of this fire is confined to the zone above the 400-foot level, and so far all efforts to stop it have failed. Operations at present under way, however, will extinguish it, quite simply and completely. We refer to the excavation by steam-shovels of the entire burning area, shipping the ore to the smelter, and using the waste to fill some of the near-by ravines. This novel project, which is estimated to take eight years, will involve the removal of some 30,000,000 tons of rock and ore, a truly great undertaking even in these days of mountains of copper and

20,000-ton concentrators. On another page of this issue we publish a short article on the Homestake fire, by Mr. R. G. Wayland, the assistant superintendent.

Public Service and Public Practice—II

In our last issue we discussed some phases of this interesting question, illustrating them by reference, more particularly, to the activities of the College of Agriculture in the University of California, and suggesting the effect of their example on the Engineering departments. On inquiry, we find that, at our State University, there is no regulation limiting the outside professional activities of any member of the Engineering departments, or of the Chemistry and Geology departments, so that it is left to the individual professor to decide how much work he will perform. Occasionally an individual has been subjected to criticism for neglecting his University duties for outside professional business, and he has been warned by his departmental chief or by the president to pay stricter regard to his proper functions. This, however, is a matter of internal policy, which is not regulated by any fixed rule. Some professors refuse to engage in outside work because it interferes with their scientific research; some undertake it only during the vacation; others undertake it only when it is offered; a few actually solicit it. Custom in this regard is much the same in other universities. In many of them the professors of engineering have accepted their appointments on the understanding that they will be permitted to practise; indeed, it is believed officially that such practice adds to their efficiency as teachers. That is a popular delusion. We believe that a professor can enrich his lectures just as much, if not more, by visiting a number of mines in a given district as by making a detailed examination of one of them. This applies likewise to mills and smelters. The details collected for a report on a specific enterprise are not usually such as can be employed advantageously in teaching, which is directed mainly to the elucidation of principles; moreover, the detailed information obtained in confidence by a consultant may not be released for public use. The young men in college are not being made into superintendents or managers, they are being prepared for the several years of apprenticeship that precedes appointment to such positions of responsibility. After all, a professor is much in the same position as an editor; both are teaching, elucidating, and interpreting; but the editor faces an adult class. If he is in search of material to aid him in his efforts to provide articles that are useful and interesting, he visits a number of mines, mills, or smelters, not one only, and he collects data that can be used for comparison, in order to interpret the trend and development of technical practice, rather than the data necessary to appraise an individual undertaking in terms of money. Editors should not engage in engineering practice, for the reasons that apply to professors. Such practice does not increase the efficiency of either; this can be maintained just as well by journeys of obser-

vation, provided, of course, that they have had experience in the field before they became either editors or professors. Next, by engaging in outside work, they become entangled with commercial enterprises of varying respectability; they may become involved, without fault of their own, in a public fiasco or a disgraceful failure, the effect of which reacts upon the journal or the college with which they are identified. It is true, the professor may compete with his own graduated students, but this argument we set aside; the objections to outside practice on the part of professors are not, we believe, based on any such motive as petty jealousy; more nearly the motive is the solicitude of graduates for the good name of their alma mater. Moreover, they have regard for the repute of their profession, and on account of that they, as we do, deprecate outside practice by professors. It is our belief that members of University faculties are called for advice largely because of the prestige of their position, rather than their exceptional fitness or skill; indeed we believe that sincere application to scientific research and to class teaching gradually unfits a man for commercial work, and that therefore the successful teacher is rarely a good technical consultant on mining or metallurgical operations. A specially regrettable phase of the question is the engagement of professors as witnesses, or 'experts', in lawsuits. They become hired advocates for one or other side; ceasing to be scientific, they become crassly commercial. In suits brought against public utility corporations, it is not uncommon to find professors serving as hired advocates to buttress an invasion of private rights; in such cases the honesty of the testimony not infrequently is ridiculed by the opposing side, and even by third parties, to the injury of the University with which the witness is identified. The most glaring examples of such scandals are afforded by apex-suits over mining properties, in which a number of honorable professors on one side swear a thing is black, while an equal number of equally honorable professors on the opposite side swear that it is white. Such exhibitions tend to disparage scientific authority, they throw discredit upon institutions of learning, they degrade the profession of mining geologist. It is high time that they were ended by agreement between the litigants to provide for testimony that is not hired by either side, but selected by the Court itself. However, that is another story. The subject is only worthy of discussion if a remedy can be devised or a principle evolved. We think it is possible to discern a basic principle for guidance amid this clash of moral and commercial interests. It is a simple one. Confine outside work to such as is of public value, that is, to such as is valuable to the community, local or national. Thus professors might serve on State and National commissions of inquiry and advice; they might be arbitrators in matters of public controversy; they might make investigations and reports for the public good, such as are initiated by municipalities or States; they might be retained to study specific mining or metallurgical operations if they have unique knowledge or experience especially fitting them, above all others, for

the task. In every case the public interest should be served by prompt publication of the results of such work; in no case should it be done confidentially for a private client or in behalf of an individual commercial interest. The idea that Professor Jones performs any public service by advising Mr. Brown to buy a given mine, or that Professor Smith does anything useful for his science or for his University when he uses his ability to support a line of argument prepared by somebody in a lawsuit, is absurd. If, on the other hand, either Professor Jones or Professor Smith, as a specialist, assists a court of justice, a municipality, or a State in ascertaining the truth, which is the primary function of the scientist, he will be doing a public service, for which he is entitled to be paid in proportion to the value of his work. We believe that if the idea of public service be adopted as the keystone of policy in regard to the outside practice of professors, and other holders of public office, it will be possible to develop a custom more honorable to all concerned and of more general usefulness than any at present in vogue. In such matters the force of public opinion will dominate; for that reason, we invite letters on the subject for publication.

Money for Europe

Amid the frothings of the Hearst hysteria it is satisfactory to read Mr. Hoover's sane pronouncement on the question of loans to Europe. He makes clear the distinction between a Government loan and commercial credits; the first leads to a persistent pauperization of the war-devastated countries, checking the rehabilitation of normal industry, whereas commercial credits, for which most of them still have the requisite assets, encourage a mobilization of domestic resources and a stimulation of productive labor. Austria, and more particularly its capital, Vienna, will need direct help—perhaps Poland also—but in the main our effort should be directed toward reorganization and resumption of industry rather than a glorified soup-kitchen kind of dole to the unfortunate peoples on the other side of the Atlantic. Any immediate charitable aid need not run into such sums as will necessitate a big Government loan, which means increased taxation for our people; such help can come from the reserves of the Grain Corporation. Now that the Treaty has become a fact, the first thing to do is to have some co-operation in financial measures, so that international exchange may be stabilized on some basis more favorable to business. On all these matters Mr. Hoover is exceptionally qualified to speak; no American, probably no European, is better informed concerning conditions in Europe, and it is much to be desired that his views be given proper attention at Washington. By the way, a few days ago a straw-vote for Presidential possibilities was taken during luncheon time at the Engineers Club in San Francisco: out of 72 votes, Mr. Hoover received 54, Senator Johnson got one, several others got one each, and one vote was marked "Any Republican".

Prohibition

The Editor:

Sir—As an old subscriber to your excellent paper, may I claim a little space to criticize your attitude on the prohibition issue. In your issue of December 13, you criticize a writer for saying that prohibition would be a loss to the country. Without going into arguments about the morality of the drink question—and let it never be forgotten that the wine and beer users of France and Great Britain were quitting themselves like men when thousands of prohibitionists were spreading discord and unrest in the United States and Canada—let us review the question of loss of revenue through prohibition.

The Allies today are faced with enormous war-debts. Business and professional men will be taxed almost beyond endurance before this debt is paid, whereas the average working-man, earning in many cases large wages, gets off scot free. What tax can you suggest that will bring in more revenue and be fairer than a heavy tax on beer and wine?

Theories pay no bills, and money must be raised. Why not make liquor a Government monopoly and charge a stiff price for it? Central stores could be established in each centre of, say 10,000 population. Put the stores in charge of a first-class Government official. Hold him responsible for the sobriety of his district. Register each customer by number and record his purchases day by day. If a complaint is made against a man for drunkenness, cancel his license, and make it punishable by a stiff fine for any man to give him liquor.

I have lived in Canada for several years under prohibition; I have read in the papers of the great benefits that prohibition will bring upon a country that adopts it; we are told that jails will be empty and crime decrease, etc. Such is not the case in Canada: crime is on the increase. We have 'blind pigs' and stills galore, and the cost of policing the Province is enormous; it far exceeds the cost of police protection before prohibition was enacted.

The trouble with the average prohibitionist is that he will not face facts. He is governed by sentiment or the fear that his family may suffer through strong drink, and therefore he argues that strong drink must be abolished, forgetting, in his ignorance, that there are evils in the world that cannot be abolished, only controlled. The social evil, as Kipling says, is the oldest on earth. Does any sensible man think it can be abolished? Marriage is in many cases a failure. Shall we abolish marriage? It is a notable fact that no great statesman or leader of

men from Jesus Christ down to the present age has ever been a prohibitionist. This party has to depend on such men as W. J. Bryan and Billy Sunday. I am sorry, Sir, to see you in such company.

We are told solemnly by the worthy prohibitionist that drink causes physical deterioration. Was this the case with the sailors that manned the British navy or the men in the trenches? Germany has not been a prohibition nation, and whatever we can say about the effects of drink on them mentally, the Germans certainly kept the world busy to lick them. The Turks are practically prohibitionists. Are they by any means a model or an efficient nation compared with other nations? It is well to bear in mind that most nations that use no liquor are controlled by people that use well and moderately the good gifts of God.

It is also well to bear in mind that most of the good reforms come by evolution. We have enacted drastic laws in England and the United States years ago, and, like the present prohibition movement, they will fail, as the churches are failing today, because instead of following a doctrine of love, they are using a big stick.

The curse of the world is the extremist. The Kaiser was a military extremist, and plunged the world in misery. Who will say that Lloyd George and Herbert Asquith were not extremists when they took the stand against a larger army and navy, which might have averted the war, as the Social Democrats of Germany were rapidly increasing and were getting tired of the Kaiser's policy?

In conclusion, Mr. Editor, I hope you will take my criticism in the spirit it is meant, without malice. There are thousands of men in Canada today who are not interested in the liquor trade, and many of whom do not use liquor themselves, who realize that the policy of prohibition for Canada is suicidal. Our hewers of wood and drawers of water came mostly from beer and wine-using countries. These immigrants are passing us up, and many of our best workmen are returning to Europe. And all this is being brought about by a well-organized body of well-meaning people who do not realize the task they have undertaken and are indifferent to anything but riding their own hobby.

I have faith enough in the old law-makers to believe that if drink is such a curse as the prohibitionists would try to make us believe, that an eleventh commandment would have been added forbidding the use of liquor. Mr. Editor, do not kid yourself with prohibition buncombe such as has been published in Canada and elsewhere.

Any sane business man in Canada knows only too well that we have suffered a financial loss through prohibition. The War caused a season of high wages, and we now have the bill to pay. It is not the time to try experiments. The British government is not asleep on financial matters and realizes that it cannot afford to lose the liquor income because a small percentage of her citizens abuse liquor. By adopting a policy of strict control, the liquor business can be handled successfully. Prohibition can never succeed, because as a famous statesman has said, "no law can be successful when opposed by a large minority".

F. J. BOURNE.

Cobalt, Ontario, December 20.

Our correspondent should not class us with prohibitionists, but only with those willing to accept the decision of the majority in this democracy. We dislike any interference with our personal habits, and in this respect we resemble other good citizens, but we recognize our obligation not to 'kick against the pricks', but, rather, goodnaturedly to comply with the law as enacted by Congress. Extremists are unpleasant people, we acknowledge, but we are not of them. We cannot accept the notion that loss of revenue is an argument against prohibition, because those living in States that 'went dry' before the Federal enactment unite in testifying to the increase of business and the improvement in public morals consequent upon compulsory abstinence.—EDITOR.]

The Industrial Conference

The Editor:

Sir—In your editorial on this subject, appearing in the issue of January 10, you call attention to the fact that the purpose of the Conference at this time is to devise machinery for the adjustment of disputes, not to discuss the causes of them. However, I take it that you will agree that the "causes" must sooner or later be found and eradicated if we are to reach a satisfactory basis for carrying on industry. My idea is that this cannot be brought about until some arrangement is reached whereby manual workers are able to see advantage for themselves as individuals, and as a class, for putting forth their best effort.

A fundamental tenet of radical labor-unionism is the principle that an irreconcilable conflict exists between the interests of 'capital' on the one hand and of 'labor' on the other; that anything that can possibly be of advantage to the employer must necessarily work to the disadvantage of the employed. To this patently unsound doctrine is added the theory that 'direct action' is labor's only effectual weapon in the struggle for supremacy, and that the end always justifies the means. It is then natural that a large proportion of even the more conservative workers honestly believe that their own interests are best served by doing the minimum amount of work for the largest wages that the employers can be forced to pay. On the other hand, it seems to me that the employer does not come into court with entirely clean

hands. Too generally in the past his policy has been dictated by opportunism. When the supply of men, who must work to live, has been plentiful and work scarce, wages have been cut and employees have been driven to greater effort. Labor efficiency has been regulated largely by the length of the daily line of applicants seeking work; a man will work harder to hold his job if there are fifty equally good men waiting for the first opportunity to take his place, for by the same token he will have just that much more difficulty getting another job if he is discharged. Just now the worker is having his turn, for there are more places than there are men, and the result is the much-decried inefficiency in mining as well as in other industries throughout the country. 'A fair day's work for a fair day's pay', while a step in the right direction, does not go far enough. There must be provision for the man who by superior skill or intelligence, or by more industrious effort, can and does do more than "a fair day's work". He must be paid exactly in proportion to the value of his service to the enterprise, while the less capable man, earning the minimum wage, must receive enough to provide the reasonable requirements of a decent existence. One step toward a solution of the present problem of industrial inefficiency is the honest application of the principle of the 'square deal'—for the employer and the employee alike. The employer is rapidly coming to the realization of this fact, but the process of convincing the worker and gaining his co-operation will doubtless be slow and difficult. Past experience unfortunately is not calculated to instill confidence in the average worker as to the likelihood of getting square treatment from the man for whom he works. The development of mutual trust seems to be the first essential.

I should like to hear the views of some of your other readers regarding this subject, particularly those who have been working to promote understanding between the working man and his employer. I think discussion in which a 'spade' is called a 'spade' will do good rather than harm.

OBSERVER.

San Francisco, January 10.

Smelting Iron Ores

The Editor:

Sir—In reply to Dwight E. Woodbridge's criticism of my letter on the smelting of iron ores on the Pacific Coast, I take it, though his wording does not leave the matter exactly clear, that he denies that magnetite un-mixed with other iron ores cannot be smelted by ordinary blast-furnace methods. If Mr. Woodbridge can give instances of where straight magnetite is being smelted economically by ordinary blast-furnace practice he will be conferring a favor on a considerable number of people, who are under the same 'delusion' as myself. It would be interesting, too, if he could give the ratio of coke to ore in the operation and the temperature at which the magnetite is reduced.

Victoria, B. C., December 31.

Chloridizing Processes

By HARAL R. LAYNG

*The revival of interest in chloridizing volatilization processes will result in a successful application of one or other of them. The failures resulting from attempts to conduct various methods on a commercial scale† were in my opinion due to lack of sufficient knowledge of the then unknown chemical reactions and of certain peculiar effects of heat.

During the early years of the European war I had the opportunity of observing the attempts made with three different shaft-furnace plants to treat antimony ores by volatilization, all of which failed. My observations of these attempts caused me to believe that the process could be best carried on in a furnace of the revolving-kiln type. I tried treating the ore in a small furnace and got such good results that a furnace 24 ft. long by 38 in. diameter on the feed and flue end and 50 in. diameter on the fire and discharge end was installed. The early work with this furnace did not result in better than 60% extractions. I found that the low heat at, or toward, the flue end caused the antimony tri-oxide fume to be oxidized to the non-volatile tetra-oxide, which precipitated in the furnace and mixed with the molten stibnite to form an almost non-volatile oxy-sulphide. This stuck to the wall of the furnace and balled the charge so much that it was necessary to shut the furnace down for cleaning purposes at intervals of a few days. I then made changes that caused the flue end to be hotter, thereby causing the ore to be heated more quickly, a procedure that resulted in doubling the capacity of the furnace and yielding higher extractions, which were eventually brought to over 90%, and, furthermore almost completely eliminated the cause of the costly shut-downs for cleaning purposes.

The operations of the antimony plant had shown me that the more rapidly the ore could be heated to a point sufficiently high to prevent harmful reactions from occurring and cause good rates of volatilization, the better the resulting extraction.

During the past two years I have conducted many tests on a number of ores with chloridizing methods and I find that in chloridizing volatilization also it is necessary to heat the ore quickly in order to prevent harmful reactions. These would probably involve the formation of non-volatile or nearly non-volatile compounds like oxy-chloride of lead, oxides of copper, or alkaline zincates, or alkaline lead silicates; also the formation of fused compounds, like, for example, sodium sulphate, which coat

the minerals in the ore and hinder the proper reactions, or prevent volatilization of the metal compound so enclosed. Slow heating not only causes low extractions, due to these harmful reactions, but also decreases the capacity of the furnace, and therefore entails an excessive consumption of fuel. It may also prevent the development of beneficial reactions.

It is probably due, mainly, to the serious effect of slow heating, especially when sodium chloride is used, that most of the large-scale attempts heretofore made with chloridizing volatilization processes have been unsuccessful. These attempts were conducted usually in rotary-kiln furnaces that were fired at the discharge end, the aim evidently being directed to economy of heat by minimizing the difference in temperature between the gases leaving the furnace and the charge entering it at the same place. Such procedure in the long furnaces required for commercial work would naturally result in the ore being slowly heated, which would cause low extractions or low furnace-capacity, and consequent failure.

The importance of rapid heating is apparently not recognized by Mr. Croasdale, who after having failed with 25-ft. furnaces now proposes furnaces of the regular cement-kiln type from 75 to 100 ft. long. Mr. Stevens also seems to favor the long kiln-furnace. G. H. Wigton in Patent No. 1,264,586 states that the ore should be slowly heated.

The fact that slow heating, especially in cases wherein sodium chloride is the chloride used, is the cause of poor results is clearly proved by tests that I conducted on a number of different types of ore. One ore gave the following analysis:

Before treatment (analysis)		After treatment (estimate per ton of untreated ore)	
Au	0.03 oz.	Au	None
Ag	10.86 oz.	Ag	None
Pb	15.78 = 10.8 % Pb*	Pb	None
PbSO ₄	2.41 = 0.38% S	SO ₄	0.95
ZnCO ₃	19.13 = 9.7 % Zn	ZnO	12.12
CaO ₂ SiO ₂	27.02 = 14.0 % SiO ₂	CaO ₂ SiO ₂	27.02
CaCO ₃	12.34 = 19.93% CaO†	CaO	6.61
FeCO ₃	21.74 = 15.00% Fe ₂ O ₃	Fe ₂ O ₃	15.00
CaCO ₃ Cu(OH) ₂	1.91 = 1.1 % Cu	CuO	0.28
Deduct error	0.33		
Total	100.00%		62.28

*Includes Pb in PbSO₄. †Includes CaO in CaO₂SiO₂.

Lead soluble in saturated brine = 14% extraction.

The loss of weight by treatment, according to the analyses, would be 37.72%. A small test made with 150 grammes of 10-mesh ore and 17 gm. of CaCl₂·2H₂O mixed with water to form a cake resulted in an almost complete extraction of lead, silver, and gold, the copper extraction being over 75%, whereas only traces of zinc were extracted. The loss of weight was 36.8%. Allowing 6.95 gm. of additional weight to the heading for the CaO resulting from the decomposition of the calcium chlo-

*The disclosures made hereinafter are subject to patent applications by the author; some of the patent applications are prepared, others are being prepared.

†'The Chloride-Volatilization Process', by Blamey Stevens, 'M. & S. P.', July 12, 1919. Also discussion of preceding by Stuart Croasdale in the issue of August 9, 1919.

ride (there was no dust loss because the charge was not rabbled, and consequently retained its original form throughout the test). The difference between the loss shown by analysis and that shown by the small test is insignificant and could be accounted for by slight variation in sampling and weighing and to moisture absorbed by the ore used in the test.

The tests shown on the charts were run on the same character of ore as shown by the preceding analysis. The charges were sampled every five or ten minutes as indicated by the station dots on the chart. Tests marked 1, 2, and 3, were made with 11% NaCl added to the ore. Those marked No. 4 and 5 were made with $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, 11% and 9% respectively. The low extraction in No. 5 was due to small amount of clinker formed and to poor mixture of lumpy chloride and ore.

These tests prove the necessity and effect of rapid heating, especially when sodium chloride is used. Test No. 5 shows an extraction line almost paralleling the temperature line, proving that the extraction can be obtained almost as quickly as the ore can be heated.

There are many ways of heating the ore rapidly; for example, a revolving furnace could be heated at the feed end; or, if a very long furnace, it could be heated at both ends. Another example would be a furnace of the shaft type, like the Stedfeldt or Scott, in which the heat is applied at any desired point. With the shaft-furnaces the extraction could probably be obtained in a few minutes, especially when chlorides of the alkaline earths are used.

The consumption of fuel in the chloridizing-volatilization process will not be a serious item. In the case of an ore somewhat similar to the analysis quoted above, to which would be added 10% of its weight of salt, the chemical consumption of heat, allowing for all thermochemical reactions, including heating of the ore, salt, and gases therefrom, to 1000°C., would amount to 701 B.T.U. per pound of ore. Allowing 100% excess air for burning fuel-oil of 20,000 B.T.U. grade and allowing the air to be pre-heated to 600°F. by means of the heat of the flue-gases, which are allowed a temperature of 700°C. as they leave the furnace, there would be 13,512 B.T.U. per pound of oil available for heating the ore and for furnace radiation. Assuming that the furnace radiation is 15% of the total heat-units in the oil, there would remain 10,512 B.T.U. per pound of oil, or sufficient to heat 15 lb. of ore. The fuel consumption would therefore be 63%.

In the case of a small multiple-hearth furnace having a capacity, with this method of heating, of one ton per day and equipped with air-cooled rables, about half of the air from the rables being returned to the furnace through the burners, but not equipped for utilizing the heat of the flue-gases other than to slightly pre-heat the ore, the fuel consumption was at the rate of 60 gal. per ton of ore. It will certainly prove advisable in practice to utilize the heat of the flue-gases for either pre-heating the air entering the furnace or for partly drying the ore, or for both purposes.

The analysis shows that the ore does not contain sufficient sulphur to complete the reactions illustrated in Mr.

Croasdale's U. S. Patent No. 741,712, and, furthermore, it clearly shows that there is no free silica, which, according to Mr. Wigton's U. S. Patent No. 1,264,586, is essential. Tests made on this ore as well as tests on other ores in which sodium chloride and sulphur or silica were used in amounts according to the reactions of Mr. Croasdale's or Mr. Wigton's patent specifications resulted in lower extractions than those of parallel tests run at the same time under the same conditions excepting for the omission of added sulphur or silica in the parallel tests.

Mr. Croasdale illustrates the principle of his patent by the equation:

In the case of a lead sulphide ore in which sodium chloride is used, the translation of the above equation would be

Such chemical change would not occur in one step; it would require two steps, as follows:

However, when lead sulphide is roasted in air, as in practice, the resulting product consists of a mixture of PbO and PbSO₄ and occasionally some undecomposed PbS. The remainder of the sulphur is oxidized and liberated in the form of SO₂. The proportional amount of PbSO₄ formed is not sufficient to cause a 'complete' extraction of the lead as lead chloride according to step No. 2; furthermore, step No. 2 is not a good reaction for volatilization because the sodium sulphate formed coats some of the lead compound and either hinders the formation of lead chloride or prevents its economical volatilization. The PbO does not combine directly with NaCl to form lead chloride, and if the PbO formed during the roasting of the PbS were coated with either molten sodium chloride or sodium sulphate (the latter from the second step) it would not be acted upon. Now, if water-vapor is present this would react with the SO₂ gas and the sodium chloride to form HCl, which would combine with any PbO, uncoated by sodium, and thereby form the volatile lead chloride. Copper ores would act similarly as in the case just mentioned with the exception that the chlorides of copper are unstable in the presence of air at the temperature required for the volatilization process and are easily converted to CuO; but when water vapors are present they would result in the formation of hydrochloric acid, which would unite with CuO to form a chloride. Chlorine does not combine with CuO at a temperature of about 400°C. when air is present, but HCl does. Chlorine does not combine with CuSO₄, either in cold solutions or heated salts, to form chlorides of copper, but HCl does.

Zinc is only volatilized in chloridizing-volatilization processes when it is in the presence of sulphur; zinc is not volatilized quantitatively from ores wherein it exists in the form of an oxide or carbonate unless sulphur in some available form is present or is added to the ore; whereas lead can be volatilized in either case. The reactions in the case of zinc sulphides could be illustrated as in Mr.

Croasdale's patent. In any case, where zinc sulphide is treated in the presence of sodium chloride, trouble from a coating of sodium sulphate is inevitable.

The process of Selden Irwin Clawson (Patent No. 1,192,037) would, in general, in so far as the reactions hereinbefore are concerned, be similar to Mr. Croasdale's. George Wigton, in his patent No. 1,264,586, among other things limits his patent to a reaction wherein a silicate like sodium silicate is formed. He then attempts to qualify this by stating in effect that by heat

But in his illustration, he publishes the reactions

This last reaction appears very doubtful. I have found in tests with ore and in tests with pure reagents that

2. Abundant lead chloride fume was given off when litharge was treated with $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, or $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ or the fused product resulting from fusing $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ at high heat. All the lead remaining was found to be lead chloride.

3. Pure galena with sodium chloride acted the same as in PbO , with the exception that the solution of the fused product contained only faint traces of lead.

4. Pure galena with $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ gave off an abundance of lead chloride fume. No fused coatings like sodium sulphate were formed. On boiling for a few minutes a saturated solution of sodium chloride containing galena, only a faint trace of lead was found in solution, whereas with both calcium and magnesium chloride solutions appreciable quantities of lead were found in solution. The magnesium chloride solution contained the most lead. The same treatment in parallel tests with the analyzed

CHART No. 1

$\text{PbO} + \text{NaCl} + \text{Heat}$ does not quantitatively result in the volatilization of lead chloride, and that whenever sodium silicate is formed the extraction is reduced as the sodium silicate increases.

I have found, both by tests on ores and by direct experiment on minerals and reagents, that the action of sodium chloride in chloridizing metallurgy differs greatly from the action of chlorides of the alkaline earths and that sodium chloride is much inferior to chlorides of the alkaline earths. By direct tests on minerals and reagents conducted in an open crucible over a bunsen burner, the results are as follows:

1. No lead chloride fume was detected when salt and litharge were heated to fusion and above the boiling-point of lead chloride. The fused product, when treated with water and the mixture boiled to saturation of the solution, showed only very small quantities of lead chloride in the solution.

ore shown in the fore part of this article resulted in 14% extraction of lead by means of sodium chloride solution, about 60% extraction with calcium chloride solution, and over 99% with magnesium chloride solution. Magnesium chloride, and in some cases calcium chloride solutions, could be used to extract the metals from some ores to better advantage than the acidified brine solutions that are usually recommended.

I have not decided as to just what reaction takes place between sulphides like lead sulphide and chlorides like alkaline-earth chlorides, but it appears that the following may be a representative reaction when heat is applied:

The H_2S would probably be further oxidized by the furnace gases. In the case of oxides like PbO the reactions would probably be

or, in the case of fused calcium chloride, it may possibly be

If the amount of water-vapor present were reduced, chlorine would be liberated instead of HCl according as the amount of water-vapor varied; in such cases the reactions would be different than those illustrated above.

The desired action of sodium chloride with ores containing little or no sulphur or silica, appears to be due to the action of some element or compound such as a form of oxygen or water-vapor contained in the furnace gases either by the aid of a catalyzer or by dissociation of

the necessity of high heat, the necessity of exposing the mineral to the gases, which is unnecessary when other chloridizing agents are used, the absence of direct reaction between lead oxide and sodium chloride, and the effects of coatings like silicates or sulphates, it is reasonable to believe that the sodium chloride is altered by the actions of the gases to a sodium compound like Na_2O and chlorine or hydrochloric acid, and the active chlorine or compound thereof attacks the lead compound to form lead chloride before the sodium compound can react with silica, lead, or both, to form fusible non-volatile compounds; also, that should the lead chloride thus formed become mixed with the other fusible compound, a great part of the lead chloride would distil out of such a mix-

CHART No. 2

sodium chloride vapor at high heat in the presence of elements or compounds contained in the furnace gases.

In many, if not all, cases wherein sodium chloride is the chloridizing agent, it is necessary to expose the ore particles to gases, like those from the furnace, containing air or water-vapor, or both, in order to obtain good extractions. It appears, in lead oxide or carbonate, that the desired chloridizing of the lead, when sodium chloride is used in the presence of gases, takes place only at high temperatures, apparently above the boiling-point of sodium chloride, which temperatures are very much greater than the temperatures required by chlorides of the alkaline earths.

The effect of slow heating is more detrimental to chloridizing volatilization when sodium chloride is used, especially in the case of lead oxide, than in the case of alkaline-earth chlorides.

Taking into consideration the effect of slow heating,

ture because of its (lead chloride) high vapor-pressure at the temperature under consideration. Sodium chloride does give good results in some such cases but the results are not as good nor are they as easily obtained as those obtained by the use of the alkaline earth chlorides in otherwise parallel tests.

With all the ores I have thus far tried to treat by means of wetting them with solutions of either calcium or magnesium chlorides and forming cakes thereby, and heating them without rabbling or disturbing the cakes during the treatment, I have gotten just as high extractions (extractions varying from 90 to 99+%) as were obtained with parallel tests run at same time but rabbled throughout and without wetting. This in the case of chlorides like alkaline earth chlorides proves that rabbling is not necessary and that it is not necessary to have each particle of ore exposed to the gases of the furnace; however when sodium chloride is the main chloridizing

agent used I found that rabbling was necessary to produce good results.

The fact that good extractions can be obtained from ore molded into cakes that only expose one face to the furnace gases and that are not broken during treatment, certainly proves how little air is necessary.

The best furnace conditions would depend mainly upon the ore or mineral and the chloridizing agent. To volatilize some metals as chlorides, reducing conditions would be necessary; whereas with other metals, neutral or oxidizing conditions would be best. In some cases of copper, or like ores, highly oxidizing conditions should be avoided. In the case of an ore like the one shown by the analysis quoted above, reducing conditions would

than do cotton bags. This fact is learned from the bleaching and cleaning industries.

In the Pohle-Crossdale plant at Mayer, Arizona*, woolen bags were used. The results there may have prompted the doubt regarding the efficiency of bag-houses.

When using bag-houses it would be a good plan to feed an alkali or an alkaline earth to the flue-gases before they enter the bags, because this procedure will not only neutralize free acid and thereby save the bags, but it will also save chlorine. It will probably be found necessary or advisable, in order to cut down the equipment and operating costs, to make an addition of an alkali or alkaline earth (as carbonate or oxide) to the

CHART No. 3

among other obvious happenings, cause the ore to slag.

Reference is made by some people to the supposed difficulty attending the collection of the fume. It is said by a few, and referred to by others, that the Cottrell system is the cure for all evils and it is also stated that that system is the only one which will successfully or advantageously collect the fume from chloridizing volatilization. These fumes are more easily collected than antimony oxide fumes, which are almost completely caught by means of properly designed chambers and bag-houses, or absorption devices, like spray or coke-towers. I have not experienced any difficulty whatsoever in preventing the escape, even to traces of chloride fume that were sent to a bag-plant. The bags will collect as much, if not more, of the chloride fume sent to them than will a Cottrell plant. I have found that cotton bags stand the chloride gases better than they stand sulphurous gases. Woolen bags will not stand the chloride fumes, although they withstand sulphurous fumes much better

furnace-gases before they enter a Cottrell plant, since free hydrochloric acid or moist chlorine gas would injure the metal parts.

A scrubbing or absorption system should prove advantageous. Such systems are cheaply erected; they require little attention; they are almost fool-proof, and are more cheaply operated than any other system. With such a system it is possible to make numerous separations. Take, for example, a lead-zinc-copper-gold-silver ore that is being treated by chloridization-volatilization. The fume, containing all the metals as chlorides, could be sent to the lower part of a tower filled with pieces of, say, limestone, over the surface of which trickles a solution, say, of calcium chloride, which is fed at the top of the tower and which after passing through the porous filling of limestone is drawn from the tower at a point near the base. The ascending gases, containing the chlorides, on passing through the porous fill, come in direct contact

*M. & S. P., September 1, 1906.

with the descending solution. Such chlorides as lead chloride are thereby dissolved in the descending solution, whereas such chlorides as zinc chloride are insoluble. Any free chlorine or hydrochloric acid in the gases reacts with the limestone to form calcium chloride or any oxy-chloride, and is thereby recovered. Calcium oxy-chloride, or chloride of lime, is an effective chloridizing agent in volatilizing processes. The valuable chlorides in the fume are recovered either as dissolved metals in the solution or insoluble salts of the metals suspended in the solution and they are removed at the base of the tower, together with any ore-dust or calcium sulphate. The solutions and the suspended particles can be treated by any one of several methods; for instance, they may be

after treatment can be returned to the tower for re-use or they can be otherwise disposed of, for example, by mixing with the ore. With insoluble anodes the precipitation is not complete, but, as the solution need not be thrown to waste, it matters but little if the precipitation is not complete so long as an appreciable precipitation takes place. Chlorine will be liberated when insoluble anodes are used, and this chlorine can either be returned to the tower or fed to the furnace to chloridize the minerals. The cathode efficiency is high when complete precipitation is not attempted. The use of insoluble anodes in this way would be cheaper than the use of soluble anodes.

When the ore contains so much sulphur as to cause un-

CHART No. 4

treated by settlers, or a series of settlers, to remove the suspended particles such as zinc chloride, which can be treated as desired to recover the zinc and the chlorine. Then the solutions may be treated with lime to precipitate the metals, and the precipitate may be treated to recover the chlorine and the metals; or they may be treated with a precipitant like lead to precipitate any silver, gold, and copper; or they may first be treated with copper to precipitate the gold and silver and then with lead to precipitate the copper. The solution containing lead chloride may then be precipitated by lime and the product smelted with an alkali or alkaline-earth carbonate and carbon to produce lead bullion and recover the chloride; or the precipitate may be shipped to the market; or the solution containing lead chloride may be treated by electrolysis to precipitate the lead. If soluble anodes are used, no chlorine is liberated and the lead can be almost completely precipitated. The solutions

CHART No. 5

profitable consumption of limestone, an insoluble filling and water could be used in place of the limestone and calcium chloride solutions. Then the zinc chloride would be the soluble chloride, as well as the copper and some silver, whereas the lead chloride would be mostly insoluble. The metals could be separated and recovered by well-known methods.

Perhaps in some cases it would be more profitable to roast the ore to remove the sulphur before commencing chloridizing volatilization. In cases where the chloride fume is caught dry, as in a bag-house, it can be treated by means of wet methods to separate and recover the metals, or the product can be smelted with an alkali or an alkaline-earth carbonate and carbon to produce bullion and an available chloride. The selection of the best means of collecting the fume and treating it, as well as the mode of application of chloridizing volatilization, depends a great deal on the character of the ore and

the local conditions under which it is necessary to do the work.

The proper degree of grinding to be applied to an ore will depend upon the character of the ore itself, the chloridizing agent, the type of furnace, and the method of applying the chloridizing agent. When sodium chloride was used I obtained better extractions from some ores when ground to pass a $\frac{1}{2}$ -inch aperture than after finer grinding. I found that the ore heated quicker and that it sintered less when coarsely ground.

The manner of applying the chloridizing agent will also depend upon the ore and to a smaller extent upon local conditions. The chloridizing agent may be added in a solid form or it may be added as a solution. Except where fuel is expensive or water scarce, it will be advisable, unless possibly the ore is to be pre-roasted before being subjected to chloridizing volatilization, to crush the ore in solution, then de-water to a desired point, say, where the proportion of solution retained is sufficient to provide the proper amount of chloridizing agent. The thickened pulp may then be fed to a suitable dryer, such as, for example, a double-action broken-flight conveyor by which ore is dried as much as desired and the lumps broken up. Such a dryer could be heated by means of the flue-gases from the furnace. The ore could then be fed to the furnace. Grinding in solution will reduce the cost of grinding by about 50%; it will prevent the dust nuisance; it will cause less loss by dusting in the furnace; it will save chloridizing agents; it will ensure a perfect mixture of chloridizing agent and the ore, thereby ensuring good extractions; and it will increase the extraction in oxidized lead ores because lead is dissolved by the chloride solution, and it can then be recovered from the decanted solutions by precipitation. In cases of oxidized lead ores chloridization will be almost complete before the ore reaches the furnace. Ores will settle well from saturated calcium-chloride solutions, especially if sodium chloride is present. A saturated solution of calcium chloride will contain 40% CaCl_2 , equivalent to about 53% $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$. I have experimented with the Cerro Gordo dump-ore, which contains considerable dust and which is somewhat similar to the ore quoted above, but of somewhat lower grade; this ore when ground to pass 10-mesh will settle readily in calcium-chloride solutions containing a little sodium chloride, to a pulp containing less than 20% solution. On drying such a pulp (containing 20% saturated solution) down to near the point of crystallization of $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, it would be necessary to evaporate 180 lb. of water per ton of ore. The dried mixture would contain about 10.6% $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, which is more than sufficient for treatment of the ore by chloridizing volatilization. The flue-gases would contain more than sufficient available heat with which to drive off the small amount of water. In this particular case, over 50% of the lead and some silver would be recovered from the decanted solutions. On this ore I have repeatedly obtained over 98% of the silver, lead, and gold contents by chloridizing volatilization. Assuming the improbable, that only 75% furnace extraction of the lead could be

obtained, then, if 50% were extracted by solutions and 75% of the remaining by volatilization, the total extraction would be 85%.

The consumption of chloridizing agents will not be a serious item of cost in the process, because there is little chance for stack losses, especially if an absorbent like calcium carbonate is used. The combined chlorine can nearly all be recovered in an available form and most of the chlorine is driven from the ore before it is discharged. An allowance of 10% of the chloride added to the ore would in most cases cover the possible losses. The amount of chloride required by the ore will vary with the character of the ore, the type of furnace, and the nature of the chloride, as well as the manner of applying the chloride. The amount added to the ore may vary anywhere from 1 to 12% or more of the weight of the ore; therefore, the loss would not exceed, say, 20 lb. per ton of ore. In most cases it will be found advisable to work with calcium chloride and in many cases the small losses of the chloride can be made up with a cheap salt, like sodium chloride, which may be added to the charge fed to the furnace. Saturated or nearly saturated solutions of magnesium chloride would be cheap where freight-rates are not prohibitive, as they can be purchased from ocean salt-factories for a few cents per gallon loaded on board tank-cars. The problem would be to get the tank-cars.

In some cases chlorine gas may be used as the chloridizing agent to advantage; for example, in the case of ores that tend to fuse when an alkaline chloride is used.

While chloridizing volatilization will find a big field in complex ores, it may also be used on simple ores, like a straight precious-metal ore, as the cost of operation is not high. On an oxidized silver tailing from pan amalgamation, in which the silver was combined with manganese, and in which no lead or copper was present, and, further, in which the gangue consisted of silica and barium sulphate, I have obtained 80% extractions on the first trial, whereas the best extraction that could be obtained either by cyanidation, concentration, or flotation, or by all three methods, was not much over 50%. The estimated cost of treating this tailing by chloridizing volatilization in a 50-ton plant was \$2.43 per ton.

The possibility of obtaining preferential extractions, say, of silver in a silver-lead ore, during volatilization is indicated by tests on an ore which, when 10% chloridizing agent was used gave over 80% of the silver and lead, and which, when only 4% chloridizing agent was used, gave over 80% extraction of silver and 37% of the lead.

Sintering or the formation of fusible silicates hinder extraction, but lead extractions usually suffer more than silver extractions in such cases. As a rule alkaline-earth chlorides will give better results even at lower heats than will sodium chloride.

The temperature required will vary according to the altitude, class of ore, chloridizing agent, and type of furnace.

The cost of the plant varies, of course, with local conditions, but a plant of 50-ton daily capacity could probably be erected at a cost of about \$750 per ton-capacity.

The Homestake Fire of 1919

By R. G. WAYLAND

*The early mining on the Homestake orebody was done with the square-set system and an enormous quantity of timber was used. This system has been discontinued in carrying up the stopes, and shrinkage stoping is employed from the sill-floor up to a point 25 ft. below the next level, leaving a crown of ore above each stope. After the broken ore is drawn and sent to the mill, a timber mat is laid on the sill-floor and the empty stope is filled with waste from the level above. Subsequently the pillars and crowns are removed by square-set stoping and filled with waste.

The fire, which is now† burning at the Homestake mine, started on the evening of September 25, 1919, above the top (sixth) floor of one of the small square-set stopes in No. 3 pillar north of the Star cross-cut on the 800-ft. level.

This stope had broken into a large area of broken ore, waste, and timber above the 700-ft. level, and the night shift was engaged in drawing this ore. The broken ore and timber had arched over and hung up about 30 ft. above the grizzly, and in blasting it down the men set fire to some of the timber. They immediately tried to draw this burning timber out, but failed, and steps were at once taken to pipe water into the stope from the 800-ft. level.

Smoke and gas from the burning timber soon rendered it impossible to work in the stope without rescue apparatus and the gas was spreading to other parts of the mine. Therefore, the work of building brattices to isolate the fire area was commenced at once. Wooden brattices, plastered with cement, were built in all openings into this part of the mine on the 600, 700, and 800-ft. levels. The increasing volume of smoke and gas soon made it necessary to use oxygen apparatus in this work also. Later it was necessary to build brattices on the 900, 1000, and 1100-ft. levels as well.

At the same time, pipe-lines were laid on the 600 and 700-ft. levels, and the area immediately over the fire was flooded with water. On the 600-ft. level a cross-cut was driven from the foot-wall into the caved ground above the fire and an attempt was made to drive a pipe ahead to a point directly over the fire and turn water into this cavity. This work was done under the direction of the Bureau of Mines engineers. Two short headers were driven on the 700-ft. level in an effort to get near the fire, and in one of these some burning timber was encountered and extinguished, but without effect on the main body of the fire. This is the only instance in which fire was actually seen since the first night.

Chemical apparatus from the Lead City fire department was used at this point and a stream was kept playing for about 24 hours without any tangible result.

In the meantime, car No. 5 of the Bureau of Mines had arrived at Lead and its crew was giving every aid in the helmet work and in devising means for combatting the fire.

On October 5, after a conference of department heads, it was decided to hang up the mills and flood the mines. On October 7 the first 12-in. pipe-line began to flow into the open-cut and on the 9th the second one. These pipe-lines were each 600 ft. long and were laid on the surface of Mill street from a point in front of the general offices into the open-cut.

A 3200-ft. flume was also constructed along the side of Whitewood creek from a point a short distance below Kirk to the mouth of Savage tunnel, which connects with the 300-ft. level of the Homestake mine. Water was turned into this flume on October 12. Water flowing in Deadwood gulch at Central City also was caught and pumped into the mine. The Golden Reward mine at Aztec, at the head of Whitewood creek, was equipped with skips and is being unwatered, the water flowing into the Savage tunnel, three or four miles downstream. The total amount of water running into the mines is about 1300 cu. ft. per minute, and the total volume to be filled is about 100,000,000 cubic feet.

Concrete bulkheads have been built in all the openings from the Homestake mine proper into the Caledonia workings, so that these workings will not be flooded. The bulkheads were designed to stand pressure that would result if the mine were filled to the 300-ft. level, and a large factor of safety was used. The lowest bulkhead is on the 900-ft. level and is nine feet thick; those on the 800-ft. level are six feet thick; the rest are five feet. In all, 11 bulkheads were built.

The concrete was mixed in a revolving mixer on the surface and transported in mine cars down the shafts to the various bulkheads. After the forms had been removed from the concrete a finishing coat was troweled on.

All electrical machinery, drilling machines, locomotives, and everything that the water would damage was removed from the mine and the levels were thoroughly cleared of trash, stray timber, and anything that could float about and cause damage. The shaft openings have been laced to keep timber from floating into them and interfering with the skips or cages.

As soon as the water is high enough in the mine the work of unwatering will begin. The main dependence will be placed upon water skips operated by five of the hoisting-engines, and upon air-lifts. The pumps will, of course, also be used as soon as it is possible.

Stamps will begin dropping almost as soon as the work of unwatering is started; and long before the mine is entirely pumped out normal production will have been reached. The company has been able to keep all of the mine and mill crews employed on the needed surface improvements and exploration work, so that the fire has had little effect upon the community.

Fighting the fire has entailed a great deal of hard, disagreeable, and hazardous work, but the mine crew has undertaken it willingly and carried it out with great resourcefulness.

*From the 'Pahsapa Quarterly'. The author is chief engineer for the Homestake Mining Company.

†The fire was extinguished early in December.

THE LA PAZ MILL.

THE ESMERALDA MINE.

Mining and Smelting Near Matehuala, Mexico

By R. B. BRINSMADE

To reach Matehuala one leaves the main line of the Laredo-Mexico City or National railway at the station of Vanegas and proceeds by a branch line for 30 km. south-eastward. The city itself has the typical flat-roofed structures of the Mexican plateau and, beyond its smelting industry, has little to distinguish it from scores of other towns of a few thousand inhabitants. I shall first describe the American Smelting & Refining Co.'s smelter, and then give a few notes concerning the neighboring mines, which furnish the bulk of its ore-supply. These are situated at La Paz and Catoree in the mountain range lying west of Matehuala and east of the main line of the National railway.

SMELTER. The smelting is done entirely in blast-furnaces, of which there are three of different sizes, the principal dimensions being as follows:

Furnace	Daily capacity Tons	Hearth at tuyeres		Number of jacket- Two tiers		Fore-hearth	
		Length Ft.	Width Ft.	Each side	Each end	Diam Ft.	Height Ft.
No. 1.....	150	7½	4	3	2	11	5
No. 2.....	250	12	4	4	2	11	5
No. 3.....	450	20	4	8	4	18	5

The east-iron baseplates of the crucible of the largest furnace rest on 18 east-iron posts, whereas those of the smaller furnaces are supported by the usual jack-screws. The feeding is done by hand, through long doors on each side of the smoke-hood, from buggies that have been filled at the ore-beds and raised to the feed-floor level by a hydraulic elevator. The column of ore is run 9 ft. high above the tuyeres and the consumption of coke is 10% on the charge, as most of the ore is oxidized and only enough sulphide is fed to make the matte to catch the gold, silver, and copper. The blast-pressure is 24 oz. per square inch. It is furnished by two Connelsville cycloidal blowers, one making 67 and the other 100 cu.

ft. per revolution, belted to a Bass 180-hp. tandem-compound engine. As a relay is a Root No. 10 cycloidal blower direct-connected to a Nordberg tandem-compound engine of 200 horse-power.

Slag from the furnace flows continuously to a cylindrical steel fore-hearth lined with firebrick and water-cooled by jets from an exterior ring of 1-in. pipe set 1½ ft. below the top rim. From the fore-hearth the slag overflows to Nasmyth slag-ears, which are hauled by electric-trolley locomotives to the dump. The matte settles in the fore-hearth and is thence tapped into cast-iron molds with ellipsoidal bottoms, 6½ ft. long by 2½ ft. wide by 1½ ft. deep, set on four wheels and holding 650 kg. When solid, the matte is dumped from the molds to the ore-bed level, where it is sprinkled with water and broken into lumps, for return to the furnace, until it runs high enough in sulphur for shipment. This means 42% sulphur, the first matte having some 10% less.

The supply of copper ore comes chiefly from the Dolores and the dry pyrite is a silver ore from the La Paz mines. When larger than a fist it is passed through a jaw-crusher; otherwise it is dumped directly from the barrows, which run on plank-platforms, at the level of the railway-car floors, over the ore-beds. The sample is obtained by taking every tenth shovel or so, when unloading the railway-cars, and wheeling it in barrows to the sampling-mill. Here the sample passes from a jaw-crusher, a bucket-elevator, and a Vezin automatic sampler into a pair of rolls. The discharge from the rolls is quartered on an iron plate to assay size by aid of a hand-sieve and a pair of fine rolls. The ore-beds have flat floors and are surrounded by walls of slag-brick.

Power is supplied by five horizontal boilers; of these three are of the return-tubular type, 5 ft. diam. by 18 ft.

long, and two are Hazleton patent boilers, 10 ft. diam. by 18 ft. long, each with a single internal corrugated flue in the lower half of the shell and a set of return-tubes in the upper half. As in the blowing-plant, the direct-current electric generators are in duplicate. The first set is a General Electric dynamo of 125 volts and 800 amp., direct-connected to an Ideal high-speed engine of 260 r.p.m. The relay set consists of two Wood dynamos, one of 40 and one of 25 kw., belted to an Atlas slide-valve engine. There is also an ice-machine, belted from an electric motor, with a capacity of one ton per day. Part of the ice is used for drinking-water, the remainder being sold in the city.

This plant has to do its own repairing, so the shops are correspondingly complete. The smithy has four 4-ft. forges and a shear-press; the machine-shop has two lathes, a planer, a shaper, a drill-press, an emery-grinder, a grindstone, and a pipe-machine.

To catch the blast-furnace dust, there is an extensive flue system. First the furnace down-comers pour some 90% of the dust into a brick settling-chamber, the floor of which is arranged in a line of hoppers that can be spouted direct into a small ear. The smoke then passes into twin flues, either of which can be cut off for repair or cleaning by a steel drop-door at its entrance. For the first part of their length, the twin flues are 16 ft. high and have a longitudinal arched roof supported by tie-rods and buckstays; for the last 100 m. or so they are 20 ft. high and have a roof of transverse jack arches. The flues have flat floors, which can be cleaned through small doors on their exterior sides. Finally the smoke escapes through an octagonal brick stack, 16 ft. inside diameter by 250 ft. high.

Altogether, the Matchuala plant is satisfactory for its purpose, which is the smelting of large quantities of low-grade copper ore, mostly oxidized and coarse, for the production of a copper-matte that serves meanwhile as a collector for dry silver ores, some of high grade. It was built by the National Metallurgical Co. under the direction of G. B. Ladd of Pittsburgh, and was acquired by its present owners in 1910.

WATER-SUPPLY. Formerly the population of Matchuala were frequently forced by thirst to migrate during the dry season, but this scarcity of water was remedied as a preliminary to the construction of the smelter. By an expenditure of \$360,000, the only mountain stream in the vicinity, for a long radius, was secured at Maroma, whence it is brought to town in a 30-km. canal, the minimum supply being 400 gal. per minute.

POWER-PLANT. Adjoining the smelter is the power-plant of the Dolores copper mine of the A. S. & R. Co., situated eight miles away on the company's narrow-gauge steam-railway. The plant is one of 300 hp. and has two Erie City water-tube boilers, fed by Knowles pumps with water from the tower outside, which cools the condensed steam from the engines. There are two Nordberg tandem compound Corliss engines, each belted to a General Electric three-phase generator of 600 volts and 212 amperes. The resulting alternating current is stepped

up to 10,000 volts for transmission and reduced at its terminal to 440 volts for mining purposes.

THE MINES OF LA PAZ. This district has two distinct classes of deposits: contact masses of copper ore and fissure-veins of silver mineral. Of the former, the chief shippers are the Dolores and the Cobriza; of the latter, the Santa Maria de La Paz, the Nueva Paz, and the Esmeralda. Other less developed mines are the Maria Luisa, the Augustias, the Perla, the Santo Niño, and the Rubi.

The Dolores mine was acquired by its present owners in 1901 and was developed for several years with a force of 2000 to 3000 men. When it reached the productive stage it was found that 700 men sufficed to get out a daily shipment of 500 tons. Whenever required, the orebodies can easily yield double this quantity.

The geology is sketched in plan and section in Fig. 1, which shows a limestone hill intruded by a laccolith of monzonite-porphry. The Dolores porphyry shows in the plan as a triangle whose sides are designated as the North contact, the South contact, and the Fault. The last has a down-throw on its east side, where lie the fissures of the silver zone. The South contact follows the direction of the limestone beds but the North contact cuts across them. The orebodies lie along the contacts and are large for this type, one having been found 300 ft. long, 70 ft. thick, and over 300 ft. deep. As the North contact of the Dolores property is a half-mile long, the South contact nearly as extensive, and there are also several limestone horizons, occurring in the laccolith, where contacts may likewise contain lenses of ore, it is evident that the area favorable to exploration is immense. The contact zone is highly metamorphosed into a hard crystalline mass of garnet, chalcedony, wollastonite, epidote, and hornblende. Where replaced by ore the contact rock shows azurite, pyrite, and chalcocopyrite, and the commercial product runs 40% silica and 3% copper, with $2\frac{1}{2}$ gm. of gold and 70 gm. of silver per metric ton. Originally the ore was shipped to Aguascalientes for smelting, and then only a sorted grade going 5% copper was payable, but since the purchase of the Matchuala smelter the shipping grade has been reduced to 3%.

The mine is opened by a vertical shaft from the surface and by two cross-cut adits, one on the South and the other on the North contact. The main shaft has two compartments, equipped with balanced two-ton skips, and is over 100 m. deep. The South adit is double-tracked and connects with a two-compartment vertical shaft also furnished with two-ton skips and over 100 m. deep. The North adit has a like shaft but with a third compartment for a ladder-way. These shafts are driven in self-sustaining rock and are consequently only timbered enough to hold the skip-guides and the ore-bins at the levels placed at 100-ft. vertical intervals.

The shafts are fitted with Wellman-Seaver-Morgan second-motion electric hoists of 125 hp. each. These have inch ropes with a maximum speed of 500 ft. per minute, wound on double 5-ft. drums. The motors are General Electric of 440 volts and a three-phase current. These

electric engines were put in a decade or so ago to replace smaller gasoline prospecting hoists. The electric current, which arrives from the generating station of Matchuala at 10,000 volts and is stepped down to 440 volts at the mine, also drives an Ingersoll-Rand air compressor capable of supplying twenty-five 3 in. piston drills at 80 lb. pressure. This machine is turned by a constant-speed synchronous motor and its air-cylinders are cross-compound, equipped with the piston-intake and an automatic release. This last opens two relief-valves when the air-receiver is overloaded and prevents the pistons from doing aught but churn the air.

Before the installation of this air-compressor, in 1911,

plays his assistants on day's pay, which is advanced by the company, as the work progresses, and deducted from the contract price on the day of settlement.

Every mine-car is sampled before dumping, and, unless all the cars from a stope are up to the required grade, the foreman also samples the face, as its appearance alone is an uncertain guide. In the assay office, the mine-run samples are only tested for copper, because each per cent of copper means 0.8 gm. of gold and 23 gm. of silver per metric ton.

In hand work, the progress is so slow that little powder is consumed and artificial ventilation is therefore unnecessary, while in development by power drills the compressed air suffices to blow out any excess of smoke. Like-wise little or no pumping is required, as the natural fissures of the contact formation suffice to keep the workings dry in this region of small rainfall. Indeed, water is so scarce locally that a considerable quantity for domestic and mining use is brought in daily on the railway from Matchuala.

The company provides a doctor and hospital for its

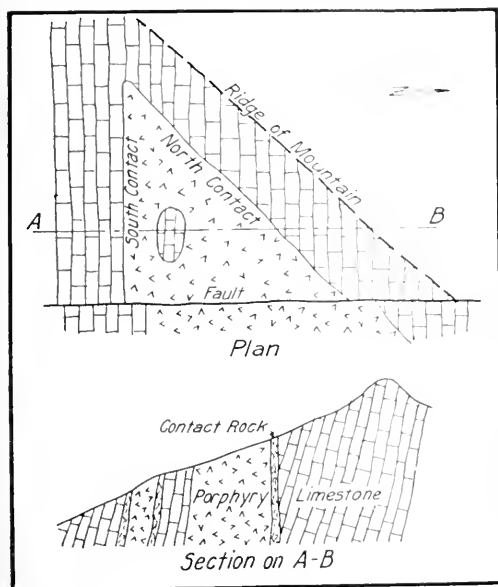

FIG. 1

all development was done by double-hand drills and was extremely slow, as a gang could only drill a metre of inch holes in contact-rock and two metres in limestone per shift. This meant a weekly advance of $1\frac{1}{2}$ to 3 metres, when working two gangs at the face of a tunnel 2 m. high by 1.8 m. wide on each of the two daily shifts. With air-drills, this speed can be quadrupled and often quintupled.

Tramming is done in Koppel side-dump steel cars, holding 840 kg. and with wheels shrunk on the axles, which run in outside boxes as in railway practice. All tramming is done by contract under direction of the company's boss. In fact, the contract system is generally used for all labor in the mine except skip-tenders and hoisting-engineers. The development is paid by metre of advance and the stoping by the ton broken. The company furnishes the contractors everything free, except explosives, which are sold at cost. Generally one contractor has charge of only one heading or stope and em-

FIG. 2

employees, who are entitled to free treatment and an allowance of money during illness by the payment of a small monthly contribution to the hospital fund. Besides an American foreman, practically all underground men are Mexicans. The official staff, which includes a superintendent, a doctor, an assayer, and a surveyor, was all American at the time of my visit.

The Dolores mine is probably the best example of a copper mine in a lime-porphry contact formation in the eastern Sierra Madre. In the large size of its orebodies and in the nature and grade of its output, it is strikingly similar to the mines of the Saan Concession in Korea.* Here, however, the area of productive contact is considerably smaller and the altitude above sea-level much higher than in its Korean counterpart.

SANTA MARIA DE LA PAZ. This mine is owned by a native company, with many French stockholders; it also owns the neighboring Nueva Paz mine. The shares are quoted on the Stock Exchange in Mexico City; the company has paid a large sum in dividends from an output of rich ore extending over many years. Quite unlike the adjoining Dolores mines, its deposits produce principally silver and gold from fissure-veins along porphyry dikes, of which there are two series: the first running from

*M. & S. P., Oct. 11 and 25, 1919, pp. 509 and 599.

north-east to south-west, and the second from east to west. The main orebodies are found along the foot-walls of the first system of dikes and occur in vertical shoots 50 to 80 m. long and $\frac{1}{2}$ to 3 m. wide, following the dip of the porphyry, which is 60° to 70° south-east. The best bonanzas in size and grade are found at the intersection of two dikes of different strike. A short distance east of the fault shown in Fig. 3 is another fault, and this latter forms the western limit of the dikes that cut the slates, schists, and limestones in the La Paz property. In depth, the orebodies are apt to be of lozenge shape and to occur *en echelon* along the propitious fissures, as in Fig. 2.

The ore is hard, with a gangue of calcite and quartz, and contains some galena, pyrite, and sphalerite, with a little chalcopyrite, besides the sulphides and sulpho-antimonides of silver that furnish most of the yield. The Santa Maria mine is opened by a vertical shaft over 500 m. deep and ships its high-grade ore to the lead smelters at Monterrey, while its common ore goes to the Matehuala copper plant. For seven years previous to 1904, the mineral output was treated in a plant at the mine, the greater part of which was still preserved at my visit, for use in emergencies.

The Santa Maria reduction works consist of a concentrating mill and a lead smelter. The mill contains a jaw-crusher, two sets of rolls, 11 Wilfley tables, and one Wilfley slime-table, besides two bucket-elevators and the necessary bins, sluices, etc. It was run by a small simple horizontal steam-engine fed by the boilers supplying the smelter. This mill evidently handled the low-grade ore to make table and slime concentrates to feed the smelter.

The smelter has three roasters and three blast-furnaces for making lead bullion. The roasters are built of the local porphyry and sandstone, with firebrick only for lining the arches and doors where high temperatures prevail. The hearths are 16 by 50 ft. and their smoke passes to a dust-flue, with adobe-brick walls and a roof of flat cast-iron plates with no buckstays, debouching into a stack built of red brick and 60 ft. high. The dust-flue is 3½ ft. wide by 5½ ft. high inside and its 20-in. adobe walls are protected by a stone coping, 12 in. wide, between which the iron roof-plates are set.

Of the blast-furnaces, the two older ones are of round section, 4 ft. inside diam. at tuyeres, and provided with four cast-iron water-jackets, 4½ ft. high, in which are set seven 3-in. tuyeres. The newest furnace is rectangular and has two tiers of four cast-iron jackets on each side and two at each end, with six 3-in. tuyeres on each side. Above the jackets, it has the usual brick shaft resting on a base of I-beams supported by cast-iron posts. The furnaces are hand-fed and their smoke debouches into an adobe dust-flue of similar construction, but of larger size, to that used by the roasters. For blast, there is a cycloidal positive blower, belted to a Ball high-speed engine, to supply all three blast-furnaces.

ESMERALDA MINE. This property, also owned by a native company, lies just east of the La Paz mine and has opened five ore-shoots along one of the north-east systems

of dikes already mentioned. These shoots are still strong at the bottom of the La Cruz shaft, which is over 500 m. deep. The country-rock here is entirely limestone and the ore-shoots lie between it and the floor of the dike. At the time of my visit, 400 tons of ore was being shipped per week with an average assay of 1.2 kg. silver per ton. Of this ore, the first-class, going 2 kg. and up, went to Monterrey, while the second-class, going around 0.8 kg., went to Matehuala. The vein-minerals are the same as those in the La Paz mine.

The steam for the power-plant is furnished by three return-tubular boilers, each of 150 hp., made by the Ames Iron Works of Oswego, New York, and fired by domestic coal. The air-compressor is of Laidlaw-Dunn-Gordon make and of 125 hp., making 1500 cu. ft. per minute; it has cross-compound air and steam cylinders and runs only the underground hoists and pumps, drilling being done by hand. The shaft head-frame is of two-post wooden type; and the steam second-motion hoisting-engine is of German make and of 80 hp., with two independent drums of 2 m. diam. which handle two one-ton buckets, in counterbalance, by a $\frac{3}{4}$ -in. rope.

THE MINES OF CATOREE. Outside of Pachuca, this district has probably produced more silver than any of its rivals in the eastern Sierra Madre. It lies on the western flank of the mountain range that contains La Paz, which is 12 miles away as the crow flies. It is reached by a wagon-road from the station of Catorce on the National railway. Leaving this valley station at an elevation around 6000 ft., the road becomes steeper and steeper as it ascends the mountain slope, finally following long sweeping curves blasted from the canyon-walls in so costly a fashion as to bespeak the ancient importance of the mines above. Twelve miles from the railway the city of Catorce itself is reached at 9540 ft. elevation, and its hundreds of snug adobe and stone houses, mostly vacant, denote the chill of the climate and the modern somnolence of the camp, a sad condition which the recent rise in the price of silver may do much to correct.

As Mexican mining districts go, Catorce is quite young, not having been discovered till 1773. Its surficial ores were immensely rich in horn-silver, and from 1778 till 1810, when the War of Independence stopped production, the gross output was over \$4,000,000 per annum, or a total for 32 years of at least \$128,000,000. Even in 1810, many of the best mines had reached water-level and sulphide ore, and after the expulsion of the Spaniards most of them remained closed for many years. In 1826, an English company installed a Cornish pump and reopened the Concepcion mine, but the pump was burnt out after a few years and little was done thereafter till in 1882 a native syndicate succeeded in unwatering part of the workings. This syndicate produced largely till 1897, when the mine was again flooded, owing to the pumps being stopped on account of the low price of silver.

Along the wagon-road from Catorce station to Catorce city are two deserted towns, formerly inhabited by the mill-hands who worked the patio process along the gulch

on the ores from the mines above. Soon after the railway reached Catorce station, 35 years ago, the richer ore began to be shipped to the Monterrey lead smelters. Since smelting began at Matchuala, the Catorce shipping ore has been packed over the mountain ridge to the east and carried 21 miles to Cedral station for smelting at Matchuala. The creek in Catorce gulch, which formerly watered the patios, now furnishes irrigation for small gardens along its banks and for some meadows near Catorce station, where fodder for the pack-animals supplying the mines is raised.

Going east from Catorce station, the wagon-road to Catorce follows the valley for half the distance and is now so out of repair as to be practicable only for pack-animals. At its mouth, Catorce gulch shows itself as an eroded antilinal fold in blue limestone, interlined occasionally with red and green shale. Half-way up the gulch to the town, large cliffs of red andesite begin to appear beneath the limestone crests of the hills, and frequent dikes of greenish diorite and light-colored porphyries are seen.

The mines lie east of town, toward the summit of the Catorce range, and occur as fissure-veins in limestone, wherever it is intruded by porphyry dikes. The ore deposits are thus, geologically, similar to the silver veins of La Paz, across the range. The Santa Ana mine is the best equipped property in the district; it has a coal-burning steam-plant supplying electric pumps and hoists installed at a cost of 2,000,000 pesos. At the time of my visit, it was the only mine that was pumping and able to extract ore below the level of ground-water. It employed 200 men and ran a horse-tramway from Catorce to the mine, a half hour's ride, for its employees. Only discovered in 1870, it has produced much oxidized ore and is now finding rich silver sulphide below the water-level. There are many other old mines, some of which have been idle for decades, owing to the expense of pumping and the cheapness of silver, that will undoubtedly be resuscitated if silver continues at its present price. Such are the Valenciana, the Dolores, the Sirena, the Boquero, the Guadalupe, the Prisca, the Padre Flores, the San Agustín, and the Purisima.

CONCEPCION MINE. As already noted, this property has been one of the most productive of the district, and, after more than a century of sporadic activity, has good future prospects. As sketched in Fig. 2, there is one fissure, called the Madre, and one developed branch, the Refugio, both opened by the main drainage-adit, a mile long and 350 m. vertically below the crest of the outerop workings at shaft No. 3. The vein is 20 m. thick and dips 64° south-west, while the limestone beds dip 30° north-west. The vein-filling is quartz and calcite except in the ore-shoots, of which there are four developed in the length of the adit and pierced by the shafts at 1, 2, 3, and 4 in Fig. 2. The distribution of these ore-shoots is apparently controlled by porphyry dikes, which cut the vein at intervals, dip sub-vertically, and are 5 to 20 m. thick. In Fig. 2, only the three principal dikes are shown at *a*, *b*, and *c*, and it can readily be seen that they

follow closely the biggest ore-shoots, at 1, 2, and 3 respectively.

The ore-shoots are not continuous chimneys, but rather form a zone of lozenge-shape lenses, $\frac{1}{2}$ to 10 m. thick and occurring anywhere between the vein-walls. They often reach a length of 80 m. and a height of 100 m., and are apt to occur *en echelon* as shown in Fig. 2. The ore-minerals are cyrargyrite, hematite, pyrobusite, and a little malachite in the oxidized zone, which extends to water-level at 400 m. vertically below the collar of the General or No. 3 shaft. Below this is a rich secondary zone of the sulphides, sulpho-antimonides, and sulpho-arsenides of silver with pyrite and sphalerite. The richest ore, often 500 oz. per ton, was found in the big lenses of shoots No. 3 and No. 4, while much ore of the lenses at No. 1 and No. 2 only assays 20 oz. At my visit, 100 men, by hand-drilling only, were getting out 30 to 50 tons weekly of sorted ore going 40 to 80 oz. of silver per ton. This was oxidized ore gleaned from the old stopes above the adit-level (as pumping the workings lower down had ceased in the 'nineties) and trammed to the mouth of the adit.

For handling the ore when working below the adit-level, there is a 200-hp. steam-hoist at No. 3 shaft; this operates two balanced buckets of two-ton capacity. As relays are two 30-hp. hoists. The surface hoists and a 160-hp. air-compressor, for mine and hoists, are supplied with steam by seven 80-hp. boilers of the horizontal return-tubular type.

The mill is a concentrator for the treatment of sulphide ores. It is equipped with a 25-hp. vertical boiler, a 15-hp. horizontal simple engine, a 10-stamp battery, built by the Pacific Iron Works, a 4-ft. Huntington mill, a two-compartment Harz jig, a 3-ft. two-field trommel, 6 Wilfley tables, and two Frue vanners. As this plant made a poor saving even on sulphides and was useless for oxidized ores, it was planned to transform it into a cyanide-leaching mill. The ore above a 40-oz. grade would then be still shipped to Matchuala, but the poorer quality of oxidized ore could be profitably leached. To reduce the cost of power, two choices were open: the first to buy electricity from the adjoining Santa Ana plant, the second to install gas-engines and supply them by coal-burning gas-producers.

AMERICAN SHEET ZINC, in exact sizes and properly marked, should be in good demand in European countries. Present conditions even favor the introduction there of American finished roofing plates. It has recently been shown that American machinery for this purpose can be much more economically operated here than that now in use on the continent. The largest use for sheet zinc in Europe is, of course, in building construction, and, strange as it may be, this field seems to be capable of worth while expansion by the United States. The American Zinc Institute is adopting publicity methods which have made so general the use of zinc construction in Europe, explaining that zinc is moderate in cost, light, easily worked, and long lived.

Tungsten in China

Tungsten mines in China were discovered only recently in deposits in the southern part below the 30th degree of north latitude. At the present time, with a few exceptions, the mines are not owned by any private companies or by the Government, but anyone may employ men to work a mine. The principal districts in which tungsten is found are in the Province of Hunan (southern part), in Hangchow and its vicinity; Kiangsi (southern part), in the Lungbauhsien, Tinan, Sintanghsien, Nankanghsien, and Taiyu districts; and Kwangtung (eastern part), in the Wuhsia, Hingninghsien, Kaiyung, Hoifung, Lukfung, and Wailia districts, (northern part), in the Nanyung, Lokchong, Chihing, and Chukiang districts. The districts mentioned above are only those in which operations are now being carried on, there being other large areas in which tungsten deposits are found, in the southern parts of the Provinces of Hunan and Kiangsi and the north-eastern part of Kwangtung, which have not as yet been opened.

Chinese tungsten, in the form of wolframite, occurs either as sands or pebbles in the streams or in small veins in the granitic rocks. The former deposits are sometimes accompanied by cassiterite or magnetite, or both, usually mixed with quartz sands, the latter in the form of veins ranging in thickness from a fraction of an inch to 2 or 3 in. Although both kinds of deposits are found in many widely scattered regions, they are never found in large quantities in any particular area. For this reason, and also because this industry is of very recent origin in China, no modern systematic methods have been inaugurated to explore this field.

Rakes, toms, and pans are used for washing the stream ores, while in the case of vein ores, hand-hammers, drills, and sometimes black powder are used for extracting the ore. With the exception of a few places in Hunan and Kwangtung, nearly all the mining is carried on by farmers, who work during their spare time after their farming labor is completed. But during the early part of 1918 the industry had grown to such an extent that many of the farmers suspended their farm work and devoted themselves entirely to tungsten mining.

The concentrate offered on the market is rather impure, and usually must be reconcentrated for export purposes. For this purpose a few native, as well as foreign, companies have sprung up, each having a concentrating plant of some sort. The Yui Hwa Mineral Supply Co. has a fairly well-equipped plant, containing shaking-screens, jigs, rocking tables, and round revolving tables for concentrating its own ores and those collected from mining centres; and it is in a position to produce concentrates of 67 to 72% WO₃ with about 5% of manganese and containing but a small amount of impurities such as copper or tin.

The farmers take their concentrate to the local market where they dispose of it to local dealers at the best prices obtainable. The local dealers, in turn, sell to licensed collectors from the ports. The port dealer has to pay

a tax to the Government, and, after shipping the concentrate to his own port, he is under obligation to export it within a certain period, usually three months. If he fails to do this he is obliged to get another license for the same ore or forfeit the ore to the Government.

According to the statistical abstracts of the year 1918, as prepared by the Chinese Maritime Customs, the total exports of tungsten ore amounted to 10,365 short tons. However, the total production for the year 1918 exceeded this figure, there being large quantities left in the mining districts which could not be sold owing to the cessation of hostilities in Europe. The working of the deposits continued, nevertheless, until February 1919, when the operators saw that the returns would not even pay their workmen. It is stated that mining operations cannot be resumed unless the market price is high enough to enable operators to pay each workman 20 tael cents per day for his labor. The following is an estimate of the cost of placing a short ton of concentrate on the market. The average rate of exchange in 1917 was \$1.08 gold, and in 1918, \$1.193 gold. The rate in the latter part of July 1919 was \$1.37 gold.

	Taels
Cost of extraction	300
Cost of transportation	40
Customs duties, license fees, local taxes, etc.....	100
Cost of insurance and incidental charges.....	20
Total cost	460

The above figure was arrived at by estimating the cost of labor at 20 tael cents per workman per day. Each workman can extract about 1½ lb. of ore per day. The cost of transportation covers the cost from the mines to Shanghai or Hongkong. The export duty on every ton of ore is about 15 taels; local taxes and license fees amount to 85 taels.

The market prices since the outbreak of the War were as follows: War-time prices, 800 to 1000 taels per ton; November 1918 to January 1919, 500 taels per ton; January 1919 to August 1919, no market in Shanghai and Hongkong, only a few transactions having taken place in Canton and Swatow at prices varying from 350 to 250 taels per ton. As evidenced by these figures, the signing of the armistice caused an almost complete stagnation of the market, which resulted in the cessation of all mining operations.

Up to August 1919 tungsten ore was wholly an export product. China has no way of utilizing the ore. A plan was formulated last year for establishing a plant at Hankow for making ferro-tungsten, but the scheme was postponed on account of the inactivity of the tungsten market. It is understood that there is a small smelting plant at Dabny, which, however, is still in an experimental stage.

It is difficult even to estimate approximately the quantities of future production for any definite length of time, as, thus far, no authoritative survey has been made of this field in China. It is estimated that all the mines in the above-mentioned districts are capable of equaling their production during the year 1918 for more than 10 years. Future shipments abroad will be governed entirely by the demands of the American and European markets.

Metal Production in California for 1919

By CHARLES G. YALE

*The output of gold, silver, copper, lead, and zinc from metal mines in California in 1919 was valued at \$23,124,045, as compared with \$31,187,807 in 1918. This is a decrease of \$8,063,762, or 26%.

GOLD. The mine output of gold for the State in 1918 was \$16,528,953. The estimate for 1919 indicates a production of \$17,320,250, which is about \$791,300 more than in 1918. Although the conditions for gold mining continue to be unfavorable, some such increase as this was to be expected in view of the fact that the decrease in the gold output in 1918, as compared with 1917, was abnormally large. The decrease in 1918 was \$4,558,551, the largest in many years, so the increase for 1919 merely shows that mining in California has begun to readjust itself to the present general conditions, and in a few years the gold mines of the State will no doubt be able again to produce their average normal annual output of about \$20,000,000. One very good indication of this readjustment is that the Mother Lode mines, which produce most of the gold-bearing ore, though still making a smaller output than usual, are materially raising the average grade of the ore per ton. Moreover, some of these mines are finding in the lower levels a better grade of ore than was found in levels 1000 ft. or more above. The gold mine with the deepest vertical shaft in the State and in the United States is now extracting from the 4050-ft. level ore of much higher average grade than any other ore found for several years, a fact that is encouraging to all the gold miners in the Mother Lode counties and that is inducing them to sink deeper workings.

The labor conditions in the gold mines of the State, though still unfavorable, were improved somewhat in 1919 as compared with 1918—that is, more skilled labor was available or the mines were worked on more nearly full time. The employers complain, however, that labor is far more inefficient now than in normal times.

The principal cause of the reduction in the gold output of the State has been that steady continuous operation of the properties seemed impossible, owing to war conditions, scarcity of competent men, high costs, and curtailment of freight and power. Some mines were worked only a few months, others were worked with only one shift instead of three, and still others have been compelled to cease work entirely for long periods. Moreover, few of the large companies were willing to push production under the increased cost and to pay the resultant war tax. Many small mines that are owned and worked by only a few men still lie idle, or partly so, most of the

output being made by the larger mines. For three consecutive years mining in California has been handicapped by dry seasons, when water for washing gravel and for operating power was abnormally scarce. The large quantity of snow in the higher mountains at the end of 1919, however, gives promise of a better water season for 1920.

The cost of producing an ounce of gold at the mine has more than doubled during the last two years, and therefore, mines that had been working on a narrow margin of profit had to cease operations. Even the best of the deep mines now being worked are making only a small profit and some are making none at all; and the mines kept in operation have not been worked to their full capacity. Few new large mines have been opened during the year and prospecting for gold has nearly ceased, for it is now almost impossible to obtain capital for investment in gold mining. Only the richest and best mines in the State are now being operated; most of the others are lying idle awaiting more favorable conditions.

In this brief review no mention can be made of conditions or improvements at individual mines. A few dredging companies have worked out their ground and closed down, but the larger companies continue work as usual and have put into operation some large new dredges. The companies have suffered from lack of competent labor and from scarcity of hydro-electric power, both of which curtailed operations to some extent, but the output of gold from dredging has fallen off but slightly. Only in this branch of the gold-mining industry is there any sign that the reduction in the output of gold is due to the exhaustion of the deposits. Two of the older large dredging fields and a few smaller outside ones show some such signs, but the largest field is showing a material increase in production. The deposits worked by dredges, however, must necessarily show, from year to year, some exhaustion, the extent of which will depend on the capacity of the dredges working them. The larger deep gold mines, however, show no signs of exhaustion thus far, and few of them have been closed down for lack of ore, the reduction in their output having been due to other reasons entirely.

At present, 53% of the total gold produced in the State is being taken from the deep mines and 47% from the placers. The dredges are producing 95% of the placer gold and about 40% of the entire gold output of the State. The placer mines are from year to year gaining in output over the deep mines. Silicious ore from the deep quartz mines is yielding 95% of all deep-mine gold, and the dredges are producing exactly the same percentage of the total output of placer gold. The leading

*Preliminary report from the San Francisco office of the U. S. Geological Survey.

gold-producing county of the State, Yuba, is entirely a gravel-mining county, where more and larger dredges are operating than elsewhere. The gold output of this county is three-quarters of a million dollars more than that of the leading deep-mine county.

It is somewhat anomalous, though noteworthy, that the number of mines reporting production during the last two years shows a large increase. Nearly all the new productive mines, however, are small, producing from a few hundred dollars to a few thousand dollars worth of gold yearly. These mines have been opened and worked by men who, being without steady occupation or incapable of more profitable work, turned to nomadic prospecting and mining. Numerous mines that have been lying idle when assessment work was not compulsory and that had been left without caretakers have been gouged and gophered for small quantities of rich ore by these nomads. Much work has thus been done, not only in old shafts and tunnels but in small gulches and in the river beds and in banks along the rivers, creeks, and gulches, by 'creviceing' and by working small gravel bars here and there, some for the first and others for the second or third time.

SILVER. The output of silver from Californian mines in 1919 is estimated at 1,121,069 oz., valued at \$1,244,386, which is 306,612 oz. less in quantity and \$193,325 less in value than in 1918. The silver produced in California is derived mainly from copper and lead ores, although some is obtained with the gold mined at placers and in deep gold mines. The principal producers of silver in California are the Mammoth, Mountain, Balaklala, Shasta King, Afterthought, and Bully Hill copper mines in Shasta county; the Engels Copper Co., in Plumas county; the Penn Copper Co., in Calaveras county; the Blue Ledge, in Siskiyou county; the Island, in Trinity county; and the Ivanpah, in San Bernardino county. These are all copper mines. The lead mines that produce silver in large quantity are the Darwin, Santa Rosa, Cerro Gordo, Tecopa, and Slate Range mines in Inyo county. These mines together produced 1,007,335 oz. of silver in 1918 and only 345,272 oz. in 1919, so the decrease from these combined properties was 662,063 oz. of silver. The output of a new productive silver mine in 1919, that of Rand Divide Mining Co., in Inyo county, served to overcome to some extent the large deficiency shown by the mines mentioned above; but this output, though comparatively large, was not sufficient to make up entirely for the loss mentioned. Of the copper and lead mines named above, some were closed entirely in 1919, and the smelters in others were shut-down for the year in April and May. All were much less productive in 1919 than in 1918. Notwithstanding the high prices of silver during the year, comparatively few of the old and long idle silver and lead mines in the southern part of the State became very productive, though a number have been and are being re-opened.

COPPER. The estimated mine output of copper in California in 1919 was 22,299,656 lb., valued at \$4,236,934, as compared with 47,674,660 lb., valued at \$11,775,641,

in 1918, a decrease in quantity of 25,375,004 lb., and in value of \$7,538,707. Plumas is the largest copper-producing county of the State, but Shasta, Calaveras, Siskiyou, and Trinity are also large producers, and small quantities are produced in most of the other metal-mining counties. The two largest copper smelters in the State, those of the Mammoth and Mountain Copper companies, of Shasta county, closed down in April and May, one because of labor troubles. The Balaklala mine, also in Shasta county, ceased operations in May also. Several other smaller mines also ceased or restricted their operations. Most of the smaller copper mines of the State stopped shipping ore almost entirely in 1919 because of the low prices for the metal and the high cost of operation, which together account for the large decrease in the copper output of the State in 1919 as compared with 1918.

LEAD. The mine output of lead in California in 1918 was 13,372,049 lb., valued at \$949,415, and the estimated output in 1919 was 4,455,161 lb., valued at \$253,944, a reduction in quantity of 8,916,888 lb., and in value of \$695,471. The output of lead in California was 8,496,579 lb. less in 1918 than in 1917, and the figures for 1919 show a decided and continued decrease. The lead is mined mainly in the southern counties of the State—Inyo and San Bernardino—where a number of the mines in the lead and zinc districts have ceased or curtailed operations owing to the high cost of labor and material, high shipping charges, and the low price of the metal. The Darwin mine, Inyo county, was closed entirely during the year and the Cerro Gordo was worked only a few months. Other large mines produced a smaller output for the year and many small properties in the counties named remained idle.

ZINC. The estimated output of zinc in the State in 1919 was 965,259 lb., valued at \$68,533, as compared with 5,561,393 lb., valued at \$506,087, in 1918, a decrease in quantity of 4,596,134 lb., and in value of \$437,554. Direct reports from the few zinc-producing companies of the State indicate an almost entire cessation of production at the larger plants. In Shasta county the Afterthought was idle throughout the year and the Mammoth most of the time; in Inyo county the Cerro Gordo was virtually idle, and the Western Metals Co. materially reduced its output.

THE TOTAL petroleum production in California during the year 1919 amounted to about 100,000,000 bbl., according to preliminary estimates by R. P. McLaughlin, of the California State Mining Bureau. The final figure will probably show that the year's output was slightly more than that of the year 1918. The total value of crude oil at the wells was about \$133,000,000, which is some five or six millions greater than the total value of the preceding year. Current statistics by private concerns disagree as to the actual amount of oil now stored, but do agree in indicating that stocks were somewhat less at the end of 1919 than at the beginning, which shows that the industry has not quite held its own.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

CALUMET & ARIZONA SHAFT-CONNECTION MADE. 'COMMUNITY WORK' AT GLOBE AND MIAMI.

The Arizona Section of the A. I. M. & M. E. recently held a well attended two-day field session at Ajo, where are centred the operations of the New Cornelia Copper Co. At the business meeting held January 5, President Winchell and Secretary Stoughton spoke at length on the aims and activities of the Institute. The coal situation, the establishment of a Bureau of Public Works, and increased co-operation among engineers were topics discussed. John C. Greenway gave a brief outline of the history of the New Cornelia property. F. Eckman, mine superintendent, described the method of blasting used at the mine, illustrating his subject by lantern slides. At the technical meeting held on the following day, the results of recent leaching experiments by the Inspiration Consolidated Copper Co., and the Arizona Copper Co., were presented. Recent leaching practice at Anaconda was also discussed. Five reels of moving pictures were shown, which illustrated the mine and plant operations at Ajo in every detail. The pictures illustrated particularly well two of the large blasts utilized in breaking the ore. It was estimated that 400,000 tons of ore was broken in the last and larger of the two. The meeting closed by a vote of thanks to the officials of the New Cornelia Copper Co. for the excellent program presented.

BISBEE.—The Campbell shaft of the Calumet & Arizona Mining Co. 'holed through', December 31. Every calculation in connection with the shaft worked out with mathematical nicety. Junction of the shaft with the raise from the 1400-ft. level was made at 575 ft. The raise met the shaft exactly making a complete shaft almost 1400 ft. deep. This eventually will be used as one of the company's main hoisting-shafts. The new shaft is approximately 3300 ft. from the Briggs and 2700 ft. from the Junction. It is connected with the former by a cross-cut on the 1300-ft. level, and with the Junction on the 1400-ft. level. The underground surveys were carried out through these two shafts and checked by plumbing the raise. Work on the shaft was started August 15, 1919. Working two shifts daily an average of 125 ft. per month was made in sinking and 140 ft. per month in the raise. W. H. Holcomb and J. B. Fox were responsible for the underground surveys; A. J. Balmforth handled the surface survey, located by triangulation.

GLOBE-MIAMI.—During 1919, Old Dominion company mined and treated 267,450 tons of ore which produced

20,000,000 lb. of copper; 99,000 tons of custom ore was treated, yielding 8,500,000 lb. of copper. Besides the copper recovered the smelter report shows the recovery of 5000 oz. of gold and 127,000 oz. of silver. Between 3,600,000 and 7,000,000 gallons of water was pumped from the mine daily during the year. Although from 1000 to 1100 men were employed, there were no fatal accidents. There have been none, in fact, for 23 months. This splendid showing is attributed by the management to the lively interest taken by the men in safety and first-aid work. Since 'safety-first' week, last October, there has been a marked decrease in accidents, even those of trivial nature. No effort was made to attain heavy production, because of the condition of the copper market, but instead of laying-off its men the company transferred them to development. During the year the shaft was sunk from the 1800-ft. to the 2000-ft. level in spite of heavy water flow. The West winze was sunk from the 2000-ft. to the 2200-ft. level and the Kingdon shaft from the 1900-ft. to the 2100-ft. level. Very little construction was done during the year. A water-softening plant for the Diesel engine and a shaft boiler-plant were installed. Erection of a filtering-plant for the concentrator was started during the latter part of the year. Miami Copper had a very satisfactory year. Production last year amounted to 55,000,000 lb., operating at two-thirds capacity since March. Development totaled 14,509 ft. in drifts, raises, and shafts, while 1250 men were employed. A steel head-frame was constructed at No. 5 shaft, 125 ft. in height and containing 175 tons of steel. The concrete hoist-house is 90 by 61 ft. Two hoists have been installed, a man-hoist capable of raising 1200 lb. at the speed of 800 ft. per minute, driven by a 250-hp. motor. The other is a skip-hoist with rated capacity of 10 tons of ore per skip, operated by a 1400-hp. motor at 1500 ft. per minute. A new crusher plant, which will consist of two units, each capable of handling 200 tons of ore per hour, or 10,000 per day, is under construction. A new change-house, three stories high, which will contain 1470 lockers, with showers and toilet facilities, is under construction. The company has adopted the policy of erecting houses for employees. Fourteen bungalows were built during the year. Twenty-seven acres of war-gardens, divided into 230 tracts, on which crops valued at \$32,000 were raised last year, was a unique feature of outside activities of the company. A canning kitchen, operated in conjunction with the garden, was used by 190 persons. The total output of the kitchen was 2500 quarts of preserves, pickles, and jellies, valued

at \$4800. This effected a saving of \$2500 to the consumers. On November 1, the Miami commercial company's store was made co-operative and it was announced that every six months there would be a distribution of net profits to employees of more than three months service. Miami and Inspiration have opened a dispensary in Miami, conducted by the hospital force for the convenience of employees of the companies living in the town and adjacent valley. The International smelter produced 161,000,000 lb. of bullion during 1919, despite curtailment of production at Inspiration and Miami, upon which International depends for its supply of concentrate. Although operating at less than 70% capacity, Inspiration Consolidated was the largest producer of copper in Arizona. An interesting experiment during last year was the treatment of oxidized ores in a 30-ton experimental plant placed in operation last July. The experiment has been quite successful, it is reported, indicating that satisfactory recovery from oxidized and sulphide ores on a commercial scale will be possible. Superior & Boston experienced the most important year in its history. Following the change of management early in 1919, a definite program of development was adopted, the known ore-reserves having been almost exhausted. Attention was given to development not only of the Great Eastern vein, but to known and unknown veins lying between the Old Dominion and Great Eastern veins on the north, and the Black Oxide and Buckeye veins on the south. One of these cross-cuts has intercepted the Great Eastern on the 1200-ft. level but it has proved practically barren at this point.

ARKANSAS

OLD DAVIS MINE TO BE OPERATED BY B. & A. COMPANY.

Mining operations on one of the oldest veins in the South-West will be resumed shortly when the B. & A. Mining Co. of Okmulgee, Oklahoma, starts its new milling plant at the old Davis mine in the western part of Sevier county, 15 miles north of De Queen and six miles north-west of Gilham, Arkansas, the nearest railroad point. The B. & A. company took over the property more than two years ago and has already expended \$150,000 on the property, building a mill and putting in modern machinery. The right-of-way for a branch line 4 miles long from the railroad to the mine has also been purchased and surveyed.

The mine will produce zinc, lead, and copper ore. The width of the ore-zone varies up to 40 ft., containing sphalerite, chalcopyrite, and galena. The zinc is in shoots following the foot-wall and the copper and lead are disseminated through the zone. The main shaft has been sunk to a depth of 170 ft. and several drifts have exposed the orebodies. The mill at the mine is equipped with jigs and Wilfley tables, and the company is considering a flotation adjunct to handle the slime of the mill. C. L. Larson, formerly with the Bunker Hill & Sullivan company, of Idaho, is manager of the mine, Ernest W. Ellis is mill superintendent, and Joe J. Sanford is mine superintendent. The directors of the com-

pany are John W. Hammond, O. F. Dickenson, W. M. Holsdon, F. P. Snider, Villard Martin, Charles Popkin, W. J. Seekatz, N. Lamberton, and Milo Brown, all of Oklahoma.

The mineral vein at the B. & A. mine was discovered more than 40 years ago in an unusual manner. Levi Davis, of Gilham, while hunting near the present site of the mine shot a deer. While he was bleeding the deer, a horse which Davis had been riding struck a piece of rock with its hoof and the peculiar glint from the rock attracted the attention of the hunter. Davis took the rock home and later sent it to a mining man who declared that it was ore. Prospecting led to the discovery of the present large vein.

MICHIGAN

LAKE SUPERIOR COPPER OUTPUT.—FRANKLIN DEVELOPMENT.

Houghton.—Neither the Calumet & Hecla nor any of its allied companies showed any increase in output in December. A number of difficulties combined to make the production smaller than in November. The Osceola Consolidated produced 55,420 tons of ore from all shafts in December. This is a decline of 4000 tons. The total output for the first 11 months of 1919 was 9,930,851 lb., so that the total for the year may reasonably be estimated at 10,730,000 lb. This means that the output of the Osceola Consolidated for 1919 was 50% below normal. In addition to the decline in the production the costs have been the highest in the history of the company and there has been no betterment in the quality of the ore. The South Kearsarge is about 'played out' and the richer territory to be tapped from No. 3 North Kearsarge has not as yet begun to show any appreciable effect on the total tonnage. The bulk of the ore comes from the North Kearsarge branch.

Ahmeek produced 59,802 tons in December. This is a drop of 10,000 tons from November. The 1919 output will total 16,907,000 lb. Ahmeek, given good market conditions and a fair labor market, can produce 30,000,000 lb. annually with costs as low as those of any mine in the district. Centennial produced 6660 tons in December, compared with 7000 in November. Centennial is one of the smaller allied companies of the Calumet & Hecla that suffers particularly from the difficulty that it is a property with ore on but one side of the shaft and with a comparatively limited number of openings in good territory.

Allouez is the only C. & H. company to make an advance in the last month of the year. The production of ore increased from 18,000 tons to 19,575. Allouez's output for the year 1919 may be estimated at 3,800,000 lb. Allouez is physically in shape to get back to a 10,000,000-lb. basis any time the metal market and the labor conditions warrant. Isle Royale output fell off in December, the total output being under 60,000 tons. The production from Isle Royale for 1919 will be 13,100,000 lb. Considering the conditions during the year this showing is remarkable. It means that Isle Royale comes nearer to normal than any of the other C. & H. properties.

Franklin's opening of the Pewabic amygdaloid from

the 39th level is in better ground than that opened above. When the Franklin was forced to suspend operations last fall the management wisely determined to continue openings in the Pewabic with the idea of carrying forward this work at comparatively slight expense and thus preparing for the future by getting as many advance openings ready as possible. The shaft was sunk below the 39th level, a cross-cut run over into the formation and from that point drifting on the vein started in both directions. Better progress has been made to the north than to the south. This is the same lode as opened in No. 1 shaft, that has furnished all of the copper ore sent

Lead ore was strong throughout the month selling at \$94 during the last week and averaging for the month, \$88.04. Production of lead ore also surpassed all previous records.

Throughout the year there has been a heavy stock of ores held in the bins of the producers as surplus stock. This has acted as a brake upon any advance in ore-prices. In addition from 20 to 50% of the producing plants were idle part of the year.

Tables showing the monthly shipments, value, and average price for zinc-blende and lead ore for the year of 1919 follow:

SURFACE PLANT AND MILL OF THE B. & A. MINING CO., NEAR GILHAM, ARKANSAS

to the mill by the Franklin mine in recent years. The Franklin has no plans for resumption of general mining and milling operations until the market promises 22c. per pound.

MISSOURI

PRODUCTION DURING 1919.

All records for ore-production were again broken in the district during 1919 in spite of the fact that the year's average prices have receded to the lowest level prevailing for a period of five years. The total of zinc-blende ore mined was 435,392 tons, and calamine 12,445 tons. This is an increase of 60,415 tons over the record of 1918 for blende ores, but calamine showed a decrease of 2200 tons from the record of 1918. There was a time when calamine ore-output had a ratio of one to ten with blende but the production is gradually becoming almost negligible.

The last month of the year showed a price of \$50 to \$52.50 for zinc-blende ore while calamine sold generally at \$35. The average for the month was \$49.21 for blende ore and \$34.43 for calamine ore. Shipments for the month aggregated 31,322 tons of blende ore and 382 tons of calamine.

	Zinc-Blende		
	Tons	Value	Average price
January	26,636	\$1,157,417	\$43.45
February	30,429	1,647,458	54.18
March	48,972	2,034,021	41.55
April	34,922	1,357,653	38.87
May	46,278	1,749,003	37.80
June	34,001	1,437,623	42.28
July	32,668	1,700,680	52.24
August	34,118	1,672,958	49.00
September	22,832	984,305	43.11
October	35,346	1,568,473	44.37
November	48,838	2,236,247	45.85
December	31,322	1,541,494	49.21
Year	435,392	\$18,997,521	\$43.63

Surplus stock at end of year 32,000 tons unsold, and 28,000 tons sold but not yet shipped.

	Lead Ore		
	Tons	Value	Average price
January	6,000	\$311,650	\$50.94
February	5,915	290,577	51.05
March	7,187	422,483	61.56
April	5,545	322,250	58.11
May	7,895	411,217	57.15
June	4,765	282,692	59.32
July	4,335	279,139	64.39
August	6,150	394,535	64.15
September	5,105	302,498	71.00
October	5,085	452,859	79.66
November	8,110	609,079	80.19
December	6,372	500,392	88.04
Year	73,070	\$4,922,961	\$67.37

Surplus stocks end of year 200 tons as against 150 tons in 1918.

NEVADA

FAVORABLE OUTLOOK AT EUREKA.—FLORENCE-GOLDFIELD
ASSIGNS LEASING GROUND.

EUREKA.—In a report on the Croesus made for Sir Donald Mann, known for his connection with the Canadian Northern railway and interested in the Croesus and Eureka King mines, Ralph W. Foster, his engineer, estimates that there is 2,368,635 tons of ore and slag of a net value of \$59,271,990 available for treatment by the Croesus company. He puts a value of \$1,600,000 on the slag dump at the old smelter, which he estimates to contain 40,000 tons. The report is based on ore exposed by the work in recent years through the Catlin shaft and in surface dumps, and does not include material used as filling for stopes in the early days. The gross value of the ore in the mine and surface dumps, and the slag pile, a total of 2,368,635 tons, is placed at \$73,483,800, with the cost of mining and treatment estimated at \$6 per ton, or a total for mining and treatment of \$14,211,000. The engineer points to the possibilities in work at greater depth and to the increase in the value of the ore as depth is gained, as shown by lateral work on the 400-ft. level and in the 300-ft. winze from that level.

TONOPAH.—The Tonopah Extension has announced that sinking of the McKane shaft will be resumed and connection made with the 1540-ft. level of the Victor shaft. This will be done in an attempt to open the Murray and other veins far west of where they have been developed.

MINA.—The 100-ton cyanide mill of the Olympic Mines Co., which was destroyed by fire on November 21, is to be re-built in the spring. The plant, built in 1916 at a cost of \$75,000, was insured for \$60,000. Development of the mine has continued since the mill was destroyed, the principal work being further exploration of a vein paralleling the main ore-channel which was opened shortly before the fire. The Olympic mine is at Onco, 25 miles from Mina in Mineral county. The Drew-Bugg mercury mine, owned by the Mina Quicksilver Co., has been taken over by H. G. Torrance of Oakland, California, a first payment of \$10,000 having been made on the purchase price of \$75,000. The mine has produced over \$200,000 to a depth of less than 200 ft. The equipment for reduction of the ore consists of two D-type retorts and 12 Joshua Hendy pipe furnaces. The ore is found in fissures in limestone and it contains in addition to the mercury, silver, lead, and gold, the value in the four metals making a high-grade product from which only the mercury is extracted. The dump at the treatment plant is estimated to be worth \$200,000. In recent months the output has been from 100 to 150 flasks.

DIVIDE.—Small seams of ore giving high assay returns have been found on the surface of the Keller lease on the Beats All claim of the Pay, adjoining the Belcher Extension on the south. The Treasure lease on the Polo claim of the Revert is reported to have opened two feet of ore assaying over \$200 in silver and gold in the bottom of a 45-ft. shaft. The south drift on the 200-ft. level of the

Caldwell shaft of the Divide Extension is 40 ft. long and high assays continue to be secured, according to unofficial reports. Work on the 45 and 100-ft. levels of this shaft continues to expose ore of good grade, with a drift on the latter level in ore for 100 ft. A contract has been let for extending the north drift on the 425-ft. level of the main shaft to cut the downward extension of the Caldwell ore-shoot. Prospecting of the outcrop of the main vein of the district continues in the Thomson, but a favorable site for sinking a shaft has not been found.

GOLD MOUNTAIN.—Because of slow progress in hard lime on the hanging wall of the vein a cross-cut has been driven to the foot-wall from the 100-ft. point in the drift-tunnel of the Washington Gold Quartz. The tunnel will be continued in porphyry lying on the foot-wall. Assays of from \$30 to \$40 were secured at many places in the lime, but the first objective, a cross vein, has not been reached. The vein is from 40 to 45 ft. wide.

GOLDFIELD.—The Florence leases for this year have been signed, the principal blocks being given to the Florence Divide, Cracker Jack, and Red Hill in the north-western part of the Red King claim. The Florence Divide secured a block covering the stope from which rich ore was mined last year, and territory north and west from the stope and extending from the surface to the 530-ft. level. The stope extends 60 ft. above the 380-ft. level. In addition to this the Florence Divide was granted a large block from the 530-ft. to the 650-ft. level containing the vein on the dip. The Cracker Jack was given what is considered the most valuable lease, extending from the surface to from 430 to 530 ft. and far into the practically undeveloped hanging wall of the vein from the Florence Divide stope. The Red Hill has the ground under the Cracker Jack block to a depth of 650 ft. There is little ore of shipping grade exposed in this part of the mine, the Florence Divide having stopped development work to extract all ore available in the closing days of the lease, but the entire territory held by the three companies is regarded as having exceptional possibilities. An unusual feature of the work started by the Cracker Jack is that an ore-shoot is being followed from the surface with a shaft. Surface prospecting with trenches also is being done by this company. Repairs to the shaft of the Great Bend have been completed, including re-timbering from the 300 to the 400-ft. level, and the east drift on the 375-ft. level is now being put in shape for resuming work near the face. The Development company has shipped 40 tons of ore from the rich shoot recently found in the Combination. No estimate of the value has been made.

ELY.—The Consolidated Copper Mines Co. at Kimberley, is working a small force, sinking the five-compartment shaft (known as the Giroux) below the 1400-ft. level to reach the sulphide zone. The water is caught on the 1200-ft. and 1400-ft. levels so the bottom of the shaft is comparatively dry and good progress is being made below the 1600-ft. level. The shaft is entirely in limestone thus far, but in the neighborhood of 1900 ft. it is expected that the mineralized zone will be penetrated.

The Nevada Consolidated Copper Co. is running six of

the eight sections of the concentrator at McGill. Repair men are overhauling one section of the rolls, taking out the rolls and elevators, and installing a 14-in. hinge mill, with Dorr classifiers, oil flotation, and Wadley tables. It is probable that the entire mill will be changed along these lines.

UTAH

DIVIDENDS DURING 1919. TINTIC PRODUCTION.

SALT LAKE CITY.—During 1919, the metal mines of Utah distributed to their stockholders a total of \$11,225,801 in dividends. The companies making such disbursements, together with the amounts, are as follows:

Bingham Mines Co.....	\$112,500
Cardiff Mining Co.....	75,000
Chief Consolidated Mining Co.....	282,950
Daly Mining Co.....	97,500

ARROWHEAD VEIN. SIX FEET BETWEEN WALLS. 100-FT. LEVEL, ARROWHEAD MINE, NYE COUNTY, NEVADA.

Eagle & Blue Bell Mining Co.....	89,314
Grand Central Mining Co.....	36,000
Iron Blossom Mining Co.....	50,000
Judge Mining & Smelting Co.....	60,000
Ontario Silver Mining Co.....	75,000
Sacramento Mining Co.....	9,000
South Hecla Mining Co.....	39,450
Tintic Standard Mining Co.....	552,109
Utah Copper Co.....	9,746,940
	<hr/>
	\$11,225,763

During 1918, the total amount of dividends paid by the metal mines of the State was \$19,511,745, while in 1917—the banner year for such disbursements—the total was \$29,339,451. The grand total of dividends to the close of 1919 is \$212,851,759.

ALTA.—According to R. O. Dobbs, manager of the Louise Mining Co., purchase by his company of the Moltke claims in this district was completed recently when the final instalment of \$40,000 was paid. The property, which consists of six patented claims, was originally owned by Henry Wagener and was worked in

the early seventies with much success. Three cars shipped in the early days averaged 900 oz. silver, 10% lead and 7% copper, while it is stated that during one season Mr. Wagener realized \$90,000 from the property. Most of the work done was comparatively close to the surface, leaving the Cardiff overthrust contact practically untouched. The new owners have been pushing work along the contact and are said now to have very promising indications, which, it is believed, will develop into a good body of ore. Fred W. Price, manager of the Price mine in this district, states that the company recently opened up a 15-ft. vein at a distance of 750 ft. from the tunnel portal.

EUREKA.—Officials of the Eureka Lily company state that the ore showing in the south drift on the 1600-ft. level is steadily improving. The vein is two feet wide at the point just reached. This orebody averages 7% cop-

per, 11 oz. silver, and \$4.60 in gold. Development of this promising vein will be pushed, and at the same time, sinking on the main shaft, which is now 150 ft. below the 1600-ft. level, will be continued. The estimated production from this district during 1919 is 265,000 tons, exclusive of iron ore, as compared with 362,494 tons in 1918. Preliminary figures indicate an output of 25,000 oz. gold, 6,800,000 oz. silver, 2,800,000 lb. copper, and 24,000,000 lb. lead for the past year. The mines that produced more than 1000 tons during the year are the Dragon, Chief Consolidated, Iron Blossom, Eagle & Blue Bell, Tintic Standard, Centennial-Eureka, Grand Central, Swansea, Mammoth, Colorado, Ridge & Valley, Empire, Bullion Beck, Gemini, and Victoria. After a brief holiday, all of the mines are again operating on a normal basis. Labor conditions are good and local operators look forward with a great deal of optimism to metal-market conditions during the coming year.

Directors of the Chief Consolidated have declared a dividend of 10c. per share, payable on February 2. Dur-

ing 1919, the company paid four dividends: the first being 12½¢ per share and the other three 6½¢ per share. While this property is the largest producer of silver in Utah and one of the largest in the United States, construction expenditures last year were very heavy, which accounts for the moderate rate of dividend disbursements. One of the largest and most expensive pieces of work undertaken last year is still in progress. This is the sinking and concreting of No. 2 shaft, which is now down 950 ft. and within a short time will be down to the 1000-ft. level, on which level a connecting drift has already been driven from the main workings.

The Jesse Knight interests of Provo have added to their holdings by the acquisition of the Tintic Central property. The Knight people have for some time been heavy stockholders in this property, and quite recently they secured enough stock to give them control. The holdings of the Tintic Central adjoins those of the Iron Blossom, through which the development of the former has been carried on during the past year. In recent years the Tintic Central has been carefully developed, first through its own shaft, down to a depth of 1075 ft., and later through the Iron Blossom.

The south shaft of the Tintic Standard mine, being sunk under contract, has reached a depth of 1200 ft. and sinking will continue. One of the most important pieces of work outlined for the present year at this property is the development of the south end, which will incidentally bring about a better ventilation of the entire mine.

PARK CITY.—During the past week announcement was made by O. N. Friendly, superintendent of the Judge Mining & Milling Co. that the Judge smelter, which has been closed since May 1919 will resume operations about the middle of January, under the direct management of John Ellsworth. Work will soon be commenced on the erection of new Dorr thickeners and filter-presses for an additional treatment of the lead-silver residues, which will also result in increased recovery of zinc. The Judge smelter handles zinc-lead ores from local mines exclusively.

WISCONSIN

DECEMBER OPERATIONS IN ZINC DISTRICTS.—OUTPUT OF LEAD, ZINC, AND PYRITE DURING 1919.

PLATTEVILLE.—The month of December brought added distress to mine operators of the Wisconsin zinc region. An acute shortage of coal compelled the Inter-State Power Co., which supplies power and light to all the mining districts, to enter into an arrangement with mine operators whereby operations in all departments were to be conducted four days a week. On the remaining three days, pumps alone were to run. Such a program necessarily imposed considerable financial loss on operators as well as the power company and discussion for a time favored a complete shut-down. This was regarded as a disastrous procedure since it carried with it the scattering of mining forces and the loss of experienced miners, of whom there are at the present time not less than 2000. Prices for zinc ore were good all month and a fair show-

ing was made in spite of difficulties, not the least of which was a period of frigid weather unlike anything experienced in many years. The thermometer ranged from 20 to 30° below zero. Especial effort was required to keep reservoirs and intakes open at mills and keep pipe connections from freezing. More coal than ordinarily required became imperative to keep ore-bins, change quarters, and offices comfortably heated. Top grades of zinc ore reached \$54.50 per ton, base, the second week of the month, which brought the premium price paid to \$56. The remainder of the month found quotations from local exchanges unavailable.

The zinc ore milled during December amounted to 11,015 tons; net deliveries to smelters, including mine-run to smelters direct, 6982 tons. The Frontier Mining Co. disposed of 2500 tons of fair-grade concentrate to the Mineral Point Zinc Co., all of which was surplus stock, thereby reducing the reserve in the field to this extent. It is believed that other stock-piles long held unsold, will come in for similar treatment early in the new year.

Producers of lead ore met with better satisfaction in the markets, the price of high-grade lead concentrate opening the month at a point in advance of \$82 per ton. The price advanced to \$85 per ton, about the middle of the month and the last week of the month found offerings of \$90 per ton, with top going at \$92 per ton, and some competition developing between the leading buying concerns. The reserve in the field, at all points, conservatively estimated, exceeded 1500 tons, at the close of the month.

Producers of zinc-carbonate ore met indifferent offers during the month, the price running from \$27.50 to \$30 per ton, base, 40% zinc, but the closing days of the month witnessed a spurt and the price reached high at \$35. Independent operators, however, had withdrawn from the market and shipments did not show the volume expected for the month.

Offerings for iron-pyrite, the bulk of which has been coming from ore-refineries, have been of an unsatisfactory nature for a long time and shipments have dwindled for several months. The reserve closely estimated indicates that there is not less than 10,000 tons of unsold pyrite at separating-plants, alone.

Shipments of zinc ore, lead ore, and pyrite, by districts, for 1919 were made as here shown:

Districts	Zinc tons	Lead tons	Pyrite tons
Benton	83,050	2,489	10,247
Galena	24,604	1,997
Livingston	21,096	309	73
Hazel Green	9,959	40
Shullsburg	8,001	473
Highland	8,045	275
Cuba City	6,904	1,404	4,975
Platteville	3,312
Linden	865	19
Dodgeville	190	30
Mineral Point	2,500
Total	166,088	7,036	17,795

The total net deliveries out of the field for the year to smelters comprise 100,703 tons zinc ore, 7036 tons lead ore, and 17,795 tons pyrite. The total production of lead ore is placed at 8600 tons; pyrite, 28,000 tons.

Deliveries of high-grade blends, from ore and magnetic separating plants, were made by the leading refiners; the Mineral Point Zinc Co., 29,097 tons; Wisconsin Zinc Co., 24,636 tons; National Zinc Ore Separating Co., 21,428 tons; Oliver Mining Co., 1930 tons; Linden Zinc Co., 3276 tons; Block-House Mining Co., 1764 tons; total, 53,130 tons. The average price paid for the year, per ton of ore, all grades was \$44.38.

Expansion of the industry is planned at all points, and a score of new power, mining, and milling plants will be

LOOKING DOWN NEW CONCRETE SHAFT 750 FT. DEEP,
CHIEF CONSOLIDATED MINE AT EUREKA, UTAH

erected within the next six months. Drills are operating extensively in the Benton, Shullsburg, Cuba City, and Platteville districts. Exceptionally rich strikes have been made at several points by the Wisconsin Zinc Co., Zinc Hill Mining Co., New Jersey Zinc Co., and the Vinegar Hill Zinc Co.

Wages are high at all mines, good shovelers earning from \$6 to \$8 per shift. Men are in demand in all the active mining camps.

BRITISH COLUMBIA

PHOENIX MAY BE REHABILITATED.—PROSPECTORS' ASSOCIATION.

TRAIL.—Nineteen Kootenay properties exported ore or concentrates for treatment in various American smelters. These exports were nearly all concentrates, although 3143 tons of high-grade ore was shipped, which at \$100 per ton would be valued at \$314,300. The concentrate amounted to 13,260 tons, which at \$250 per ton would total \$3,315,000. The total exports for the Kootenay-Boundary district are valued at \$649,300.

Referring to ore and concentrate the production of the district for 1919, inclusive of a few outside shippers, follows:

	Mines	Tons ore	Tons concentrate
To Trail smelter.....	134	392,580	10,972
To Granby smelter.....	3	156,821
To American smelters.....	19	3,143	13,260
Total	156	492,544	23,332

GRAND FORKS.—Since the closing down of the Phoenix mines of the Grandby Consolidated, with the result that the formerly busy town of Phoenix now is deserted, there have been reports that the company has plans which will rehabilitate Phoenix to some extent. The assertion now made is that the company proposes the installation of a concentrating plant at or near Phoenix for the handling of the low-grade ores of the mines. The volume of water necessary is said to be available. Such action, it is pointed out, might lead to the resumption of smelting at the Grand Forks smelter.

NELSON.—The British Columbia Prospectors' Protective Association has been organized with a membership of 85, with headquarters at Nelson. The officers are J. W. Mulholland, president; C. E. Crossley, vice-president; Fred A. Starkey, secretary; and Dr. R. E. Morrison, treasurer. The objects of the organization as outlined are: to deal with the matter of grants from the Government for roads and trails to mining properties; to continue the agitation for a Government ore-testing plant in the Kootenay district; to advocate the re-opening of dormant crown-granted mineral claims; to secure free sets of surface samples for purposes of study by prospectors; and to take the necessary action to have prospects examined by the district engineer, or by an engineer representing the association.

SANDON.—The Soho mine, which adjoins the Rambler Cariboo, in the Sloean district, has been re-opened after 18 months of idleness. There are four veins on the property, the two principal being the Tom Moore, upon which over 3000 ft. of development has been done, and the Soho, on which are a 100-ft. shaft and two drifts. Two cars of ore was taken out during the sinking of the shaft. Some \$60,000 worth of high-grade has been taken from the property, and there is a dump of milling ore, having an estimated value of \$10,000. Eight inches of high-grade sulphide, unusually rich in silver, has been struck at the Ottawa mine, which is being worked by Pat Maguire and A. L. McPhee on a lease from the Consolidated M. & S. Company.

STEWART.—The first shipment of ore under the new ownership has been sent from the Premier mine to the Tacoma smelter aboard the 'Prince Albert'. The shipment consisted of 225 tons, having an estimated value of \$450 per ton, the total value amounting to more than the Neill syndicate paid for the property.

MERRITT.—On the last Saturday in the old year the miners of this district organized a union, to be known as the Nicola Valley Mine Workers' Association. David Coupland is president and James Gaeter is secretary-treasurer.

AINSWORTH.—The Florence mine, Princess creek, has resumed operations, after a shut-down made necessary by the recent cold weather. The intensity of the cold may be judged from the fact that running water in a pipe two feet in diameter froze solid. A new hole of milling ore, eight feet wide, has been found in the No. 5 tunnel.

ONTARIO

METAL OUTPUT OF CANADA DURING 1919.—LABOR CONTROVERSY AT COBALT.

A statement by John McLeish, of the Division of Mineral Resources and Statistics, Ottawa, estimates the value of the total mineral production of Canada during 1919 at approximately \$167,000,000, as compared with \$211,301,897 in 1918. During the past four years the mineral production increased from \$128,863,075 in 1914 to the high-record figures of 1918, under the stimulus created by the War demand. With the close of hostilities came an almost immediate cessation of the demand for nickel, copper, lead, and zinc, with large stocks on hand. The result was a considerable falling off in production, especially in nickel, the output of which dropped from 92,507,293 lb. in 1918 to 43,000,000 lb., and copper, of which 118,769,434 lb. was produced in 1918 as against 81,500,000 lb. last year. Gold and zinc are the only metals showing an increase, the value of the gold output being estimated at \$16,275,000, as against \$14,463,689 in 1918. The output of silver dropped in volume from 21,283,979 oz. to 13,500,000 oz., but the decrease in quantity will be to a large extent counter-balanced by the increase in price. Coal production amounted to 12,500,000 tons, as compared with 14,997,926 tons in 1918.

PORCUPINE.—The Hollinger Consolidated had a record output for 1919. The total production is unofficially estimated as approximately \$7,000,000, this estimate being based on official reports covering the first 36 weeks of the year. The output for 1918 was valued at \$5,752,370. The aggregate production since the mill began operating in 1911 amounts to \$32,430,753, and the dividend disbursements to \$11,146,000. The company is now treating between 2700 and 2800 tons of ore per day. Among recent improvements undertaken in order to reduce operating costs is the change in the main haulage from the 425-ft. to the 500-ft. level, which will centralize the work.

GOWGANDA.—A complete mining plant has been installed at the Silverado, where excellent progress in development has been made. The shaft is down 60 ft., at which depth five calcite veins are in evidence. At the Kells claims, recently secured by Governor Smith of Vermont and associates, a steam plant is being put in. Considerable high-grade ore is in sight. It is expected that shipments of ore will be made from the Walsh claims in about a month. The Camburn has proved a disappointment. Work has been discontinued and the plant removed.

COBALT.—The McKinley-Darragh has issued a financial statement as of December 15, in which a surplus of \$493,995 is shown. This equals two year's dividend requirements at the current rate of 3% quarterly. In addition, the present output is resulting in profits adequate to meet dividend requirements as well as adding a small amount to the surplus. The Northern Customs concentrator has made a second payment on the purchase of the Chambers-Ferland. The purchase price is \$155,000. Of this, \$50,000 has been paid. The Cobalt Miners' Union has voted in favor of breaking away from the In-

ternational union. At present considerable controversy centres about the question of a future course or policy.

SONORA

TROOPS RESTORE ORDER IN CANANEA.

DOS CABEZOS.—The lessees of the Dos Cabezas mine, Alfred Paul, Millard Haymore, and Frank Whalen, are making regular shipments of concentrate by way of Douglas to the El Paso smelter, packing 132 miles from the mine, which is on the western slope of the Sierra Madre range. The old mill on the property has been rebuilt to combine flotation and water concentration. Excellent recovery is being made. Thirty men are employed by the lessees in mine and mill. Mr. Whalen has active charge of the property. Dos Cabezas is the property of the Pearson Syndicate, a British corporation operating mines and lumber mills in the State of Chihuahua. It has been worked for many years and has large bodies of silver-lead-gold ore developed. The main shaft is 500 ft. deep with several thousand feet of drifts and cross-cuts underground.

CON. VIRGINIA.—Roy R. Belknap and John Cleveland have reached here from Bisbee to take charge of mining and development work for L. C. Shattuck, of Bisbee, who recently bonded the Con. Virginia from Ygnacio Soto of Douglas. A force of 20 men will be employed at first. Mr. Soto accompanied Messrs. Belknap and Cleveland as far south as Moctezuma in order to have necessary legal details attended to before they took possession of the mine. Con. Virginia is a gold-silver prospect on which only shallow workings exist at the present time, but for which a great future is predicted by those in a position to know.

CANANEA.—The arrival of troops and the issuance of an injunction against the municipal government by the Federal Judge at Nogales, Sonora, to restrain it from putting into effect the order issued last fall that all Chinese merchants must go out of business here with the close of 1919, has returned Cananea to normal conditions once more. The Chinese are doing business as usual and public sentiment against them appears to have died down considerably. A message from Governor Adolfo de la Huerta of Sonora, to Julian S. Gonzales, presidente municipal of Cananea, requested that the people be patient and await action of the Federal Congress before which a resolution cancelling the treaty with China is pending. The effects of the anti-Chinese campaign in Cananea are in evidence in every mining camp of the State where the Celestials occupy the position of principal merchants, restaurant keepers, and leaders in other lines having direct bearing on the cost of living. Mistreatment of Chinese is reported to be common. Although forced to pay higher taxes than natives they manage to undersell them as a general thing, and as a result the Chinese receive the bulk of the native trade. The Cananea Consolidated Copper Co. now is employing only 3100 men. In order to relieve distress among men thrown out of employment by this reduction, the municipality of Cananea is doing a considerable amount of street repairing.

PRODUCTION OF GOLD AND SILVER IN THE UNITED STATES IN 1919

The Bureau of the Mint and the Geological Survey have issued the following preliminary estimate of the production of gold and silver in the United States during the calendar year 1919.

State or Territory	Gold		Silver	
	Fine ounces	Value	Fine ounces	Value*
Alaska	437,131	\$9,036,300	1,072,137	\$1,201,705
Arizona	202,038	4,176,500	1,266,769	4,816,033
California	840,758	17,380,000	1,201,001	1,319,508
Colorado	470,998	9,736,100	6,011,911	6,775,138
Georgia	48	1,000	10	41
Idaho	34,363	710,400	6,012,016	6,772,191
Illinois	2,393
Maine	5	100	1,112	4,643
Michigan	375,281	420,437
Missouri	5	100	50,160	66,646
Montana	119,085	2,461,700	11,910,527	16,716,090
Nevada	230,004	4,754,600	7,312,154	8,196,161
New Hampshire	730
New Mexico	28,817	595,700	712,791	798,032
North Carolina	48	1,000	49	55
Oregon	51,848	1,071,800	223,578	250,597
Philippine Islands	39,962	826,100	11,392	16,131
Pennsylvania	78	87
South Carolina	5	100	4	4
South Dakota	254,820	5,267,600	122,161	136,028
Tennessee	256	5,300	93,087	104,337
Texas	53	1,100	540,239	605,527
Utah	104,137	2,152,700	11,906,152	13,345,010
Vermont	10	200	1,819	2,039
Virginia	8	9
Washington	14,987	309,800	316,078	354,220
Wyoming	15	300	41	46
	2,829,395	\$58,488,800	55,285,196	\$61,006,412

*Valued at the average New York price of fine silver, \$1.2085 per ounce.

These figures, compared with those for 1918, show a reduction in the output of gold of \$10,157,900 and in that of silver of 12,524,943 ounces; compared with those for 1917, they show a reduction in gold of \$25,261,900, and in silver of 16,455,166 ounces.

ARIZONA

Chiricahua.—The Hill Tops Metals & Mining Co., of Chiricahua, Arizona, is considering the building of a reduction plant at its mines and the construction of a railroad from its property to San Simon.

Kingman.—The new shaft in the Green Quartz Mining Co.'s vein has reached a depth of about 35 ft. and is in four feet of ore running about \$15 per ton in gold.

Phoenix.—Development at the United Arizona Copper Mining & Smelting Co.'s property, situated 35 miles northeast of Phoenix which has been delayed by washouts, is to be resumed upon the completion of repairs to the road and bridge. A double-compartment shaft is being sunk and is now down 875 feet.

Prescott.—The Silver Cycle Mining Co., of Prescott, Arizona, will build a mill and small smelter, and install an aerial tram at its Dunkirk mine, situated in the Senator district, south of Prescott, according to O. O. Smith, superintendent.

Ray.—It is announced that the Arizona Hercules Copper Co. has temporarily suspended operations. In the meantime there are to be some changes in the mining and milling methods. The company has announced that upon the resumption of operations the wages of miners will be according to the sliding-scale which at the present price of copper

would yield a bonus of less than \$1.70 per shift which the company has been paying. About 300 men were affected by the shut-down.

CALIFORNIA

Allegany.—Work has been resumed at the Tightner mine under the management of A. Hall. It is reported that the orebody has been recovered. Preparations are being made for more extensive work by the Mariposa, El Dorado, and several other local companies.

Portola.—The Walker Mining Co. has arranged to increase the capacity of its flotation plant to 200 tons per day, and to build an aerial tramway from the mine to Spring Garden, eight miles distant. The tramway will eliminate the costly 25-mile haul to Portola. The main orebody is said to have been proved for a distance of 800 ft. by drifting, and for an additional 900 ft. by diamond-drilling. It has an average width of 16 ft., according to late reports.

COLORADO

Mayday.—Wynn and Marr have secured a contract from the Lewis Mountain M. & M. Co., and will extend the Ten Broeck tunnel 200 ft. farther on the vein. This tunnel is 3000 ft. long and was driven to cross-cut the vein at depth. The vein is said to be 2 ft. wide, assaying \$70 to \$126 per ton.

Ouray.—Luna and Eckman are getting out ore from the Wedge

Silverton.—The snow on the ground is so deep that many prospects have been abandoned for the winter. Aside from the Southwestern company's operations on the Iowa Tiger, there is little production at the present time.—Dora Consolidated M. & M. Co., Anvil Leasing Co., and Reid leases on the Champion ship an occasional car of ore.—The Little Nation Mining Co. is now operating on the Royal Charter getting out a large tonnage of ore.—The Gold King Extension Mines Co. has opened the road to Gladstone, and is running the mill.

Telluride.—Production from the district is at a low ebb. The Tomboy Gold Mines Co. had a breakdown shortly after starting up the new mill, with the result that there was no production for a period of two weeks, but the mill is now running steadily.—The Smuggler Union Mining Co. has purchased a saw-mill near Rico.

IDAHO

Coeur d'Alene.—Frank M. Smith, assistant director of the Bunker Hill & Sullivan smelter, has been in the Coeur d'Alene district acquainting himself with ore production of the district. The Bunker Hill smelter has launched out into the custom smelting business and is looking for custom ores to treat at its Kellogg plant.

A consolidation of the stock interests and holdings of the Black Bear Mining Co. and the Flynn group in the Coeur d'Alene is being negotiated. A consideration of \$250,000 is said to be involved.

Gem County.—The Zulu silver mine at Pearl, under development by Walter H. Hill of Boise since last April, has shipped some ore to Utah smelters. An operating company has now been incorporated under the name of the Zulu-Pearl Mining Co. and arrangements have been made for the build-

ing of a 50-ton mill. Some high-grade silver ore, running up to 600 oz. silver, has been opened in this mine during the last few months, according to Mr. Hill.

MONTANA

Butte. The Oresco and Heany shafts, being equipped by the Butte & Superior are about ready to start operations.

The Anaconda company is building a Bradley fertilizer plant at Anaconda to utilize sulphuric acid manufactured at the smelter and phosphate rock shipped from Idaho, to make super-phosphate.

The bond issue of the Tuolumne Copper Co. has been authorized at the stockholders' meeting in Phoenix, Arizona. The bonds amount to \$50,000 convertible into stock at \$2 per share and bear 7% interest.

The Butte-Elk Park Extension Mining Co., which is developing a group of claims one mile from Elk Park station on the Great Northern railroad, is re-timbering the 120-ft. shaft. The old 6 by 6-in. hewed-timber put in when the locators sank the shaft, is being replaced with 10 by 10-in. Oregon fir. As soon as a coal supply is assured the sinking of the shaft will be resumed. The shaft is 400 ft. deep at present and is to be sunk 800 to 1000 ft. deeper and the ground explored at depth.

Hickey Brothers, pioneers of Butte, are to resume the development of the Hlonolulu claim in the extreme eastern section of the district. They are driving a tunnel to cross-cut the vein and then they purpose to drift east.

Pat Keeney and associates have sunk the shaft on the Syndicate lode to the 150-ft. level and are cross-cutting north and south to the veins that traverse the ground. This claim is south and east of the Davis-Daly and west of the Anaconda company's Belmont mine.

The Great Butte company has suspended operations and sold all supplies and equipments. This concern was developing a group of claims about three miles north and east of Butte. They sank a shaft 2000 ft. and did extensive drifting, but did not develop any workable orebodies.

NEVADA

Gold Circle.—On the 300-ft. level of Missing Link claim of Big Chief Consolidated a shoot of \$200 ore is under development. The shaft is to be sunk to 400 ft. following the placing of new pumping equipment. Sinking is in progress from the 260-ft. level of General Grant claim on a vein 9 to 11 ft. wide.

Mina.—H. G. Torrance, of Oakland, California, has purchased the Drew-Bugg cinnabar property 12 miles east of Mina. The purchase price is said to be \$75,000, with \$10,000 as the first payment. In addition to quicksilver the ore carries gold and silver. It is the plan of the new owner to immediately install a 50-ton flotation plant. Later on a furnace for reduction of the cinnabar is planned.

Sunshine.—J. B. Ratliff and associates are preparing a shipment of silver-gold ore from a lease on the Gem Five. The ore is said to assay \$100 to \$500 per ton with silver predominating.

WASHINGTON

Colville.—A mountain top consisting of 30,000 tons of dolomite was blown up at noon on New Year's day at the dolomite quarries east of Colville. For two months the Tulare Mining Company has been preparing for this explosion. At 12:30 o'clock New Year's day the mountain top was 'dislocated' by the discharge of 7150 lb. of 10% giant-powder set off by firing 100 lb. of 40% powder. The explosion was divided into two charges placed 26 ft. apart in the mountain cliff, which was entered by a tunnel 41 ft. long, 3½ ft. wide, and 5 ft. high. After the charges were placed the tunnel was completely blocked and the powder was exploded with a blasting-battery and electric caps.

Personal

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Howard D. Smith has returned from New York.

Oscar H. Hershey is spending this week at Kellogg, Idaho.

Oscar Laehmann is at St. Louis, on his way to New York.

H. D. Quimby has gone to Spokane, on his way to New York.

Edwin O. Holter and Harold Kingmill are at Eureka, Nevada.

R. C. Gemmell has returned to Salt Lake City from San Francisco.

H. R. Hanley has gone to the New Cornelia and other mines in southern Arizona.

E. L. Newhouse, son of Edgar Newhouse, of the A. S. & R. Co., was in San Francisco this week.

Frank A. Moss, of Perth, Western Australia, is here, to visit his son, who is a mining student at Berkeley.

W. H. Blackburn, general superintendent for the Tonopah Mining Co., has gone to the Eden mine, in Nicaragua.

J. W. Richards has taken his son Percy J. Richards into partnership in his business as assayer at Denver, Colorado.

J. Harvey Whiteman, president of the Tonopah Mining Co., has returned to Philadelphia after a short visit to San Francisco.

W. A. Laddell has been appointed manager of the engineering department of the Mine & Smelter Supply Co., with headquarters at Denver.

E. H. Finch has been appointed chairman of the Mineral Division, Land Classification Branch, U. S. Geological Survey, as successor to A. R. Schultz, resigned.

Percival P. Butler, assistant superintendent of the Copper Queen smelter, has returned to Douglas from Los Angeles, having recovered from the effects of an operation.

W. C. Humphrey, general manager of the Gueriguito mine in Sonora, has returned to Douglas, Arizona, to make his headquarters, after several years residence at Los Angeles.

George Gmahling, for some time employed as brick-foreman at the Calumet & Arizona smelter, sails this month for Peru to have charge of similar work at the new smelter of the Cerro de Pasco company.

George Motz, mining superintendent of the Nacozari Consolidated Copper Co., has returned from a visit in Texas and has gone to the company's property near Pilares de Nacozari to supervise the resumption of operations.

F. M. Brown, for many years supply-agent for the Chino Copper Co., at Hurley, New Mexico, has been promoted to the position of assistant purchasing-agent for the Utah Copper Co. S. D. Akeroyd has succeeded him at the Chino.

Walter Fitch, Sr., has retired as general manager for the Chief Consolidated Mining Co. at Eureka, but will continue to serve as president. Cecil Fitch has been appointed general manager of the property, and J. Fred Johnson will be superintendent.

William B. Gohring, for 14 years connected with the Calumet & Arizona Mining Co., has resigned his position as mining superintendent, effective January 3, to engage in business for himself with headquarters at Tucson, Arizona. He was succeeded by E. E. Whiteley, the assistant superintendent.

Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

January 13.—Copper is in good demand. Lead is active and strong. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 6, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (400 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

Taking into consideration past experience in Liberty bonds and the vicissitudes of the bond market, it is believed the outstanding war issues have seen their worst prices and that within a few months a decided turning point will be manifested in all classes of Liberty bonds and Treasury notes. This conviction is strengthened by the steps being taken to free Liberty bonds from artificial support, by gradually decreasing their use as collateral for bank loans, leaving the bond market to reflect legitimate investment demands. Funds set free from speculation will inevitably seek lodgment in high-grade investments.

The Treasury with its bond-purchase fund had purchased up to November 15, from War Finance Corporation, which has operated to support the market for Liberty bonds, \$553,080,500 of first, second, third, and fourth loan 4% and 4½% bonds. These bonds have been retired and canceled. Similarly with funds returned to the Treasury in repayment of loans made to the Allies there have been purchased, retired, and canceled, \$44,812,150 Liberty third and fourth loan 4½% bonds. This bond-purchase fund will expire one year after the termination of the War.

By act of Congress March 3, 1919, a more scientific plan for retirement of the War Debt will become operative beginning July 1920. For each fiscal year thereafter until the debt is discharged, an amount equal to 2½% of the aggregate of bonds and notes outstanding, less the par amount of obligations of foreign governments held by the United States, on July 1, 1920, will be appropriated and become available for such a sinking fund. It is calculated that this sinking fund will retire foreign war debt of the United States in about 25 years, except with respect to an amount of Liberty bonds equal to loans, or cash advances to foreign governments outstanding July 1, 1920. When and as these foreign obligations, which on December 17, 1919, totaled \$9,443,005,329, bearing 5% interest, are repaid to the United States, an offsetting amount of Liberty bonds may be purchased and retired in advance of their maturity. Annual interest due the United States on these loans to the Allies will, when paid, considerably exceed our present prescribed sinking fund.

Estimated expenditure for the bond-purchase fund is \$740,000,000 for the fiscal year ending June 30, 1920, and the estimated appropriation for sinking fund is \$287,500,000 for the fiscal year ending June 30, 1921.

Discussing respective values and yield of war issues at present, C. F. Childs & Co. of New York, point out that the United States notes and bonds of the Third Liberty Loan are today quoted at prices to net the investor more than 5%. The former have not been supported by Government purchases. These two issues virtually represent the present credit-level of the Government based upon a supply and demand market. It would, therefore, seem reasonable that a similar parity yield may develop with respect to the market for Second and Fourth Liberty Loans. Should Federal Reserve banks eventually advance their discount rate to 6%, which would not be likely to hamper trade, such a rate would tend temporarily to subject all non-mercantile loans to more careful scrutiny and the bonds of all Liberty loans would be adjusted to prices reflecting a more correct and equalized market level and showing more uniformity of income yields. However until the Government's purchases of the different bonds is discontinuantly made, there will probably be a marked difference between the yields of the several issues.

Foreign exchange quotations on January 13 are as follows:

Sterling, dollars: Cable	3.74½
" Demand	3.74½
Francs, cents: Cable	8.93
" Demand	8.91
Lire, cents: Cable	7.45
" Demand	7.45
Marks, cents: Demand	2.06

Eastern Metal Market

New York, January 7.

Due largely to highly speculative markets in London, the metal markets here are in most cases buoyant.

Copper is the least affected by foreign speculation, but is strong and higher.

Buying of tin by consumers is light but prices are soaring, due to higher foreign quotations.

The lead market is the strongest of all, with supply inadequate and prices advancing.

The zinc market has started the present week with wide advances, due to foreign demand and speculation on the other side.

Antimony is quiet but stronger.

IRON AND STEEL

Inquiry for both export and domestic consumption in the first week of the year has been heavy in all the principal markets. On much of it the mills have been unable to quote. Scarcity prevails in bars, pipe, sheets, rods, wire products, and semi-finished steel. More is heard of reduced operations at automobile plants because of a lack of steel. Car shortage is causing trouble also.

Pig-iron output in December, according to 'The Iron Age', was 2,633,268 tons for 31 days, or 84,944 tons per day, indicating a further recovery from the effects of the coal strike. The November output was 2,392,350 tons or 79,745 tons per day. Estimating charcoal pig-iron at 360,000 tons, the 1919 output was close to 31,000,000 tons as compared with 39,054,000 tons in 1918.

Definite orders for 250,000 tons of rails have been placed in the Chicago district on which rolling will commence at once. In addition tentative orders call for 100,000 to 150,000 tons more.

COPPER

Demand from both foreign and domestic consumers is reported as still excellent and likely to continue through January at least. Buying in November and December is estimated to have totaled 450,000,000 lb. Stocks on hand are still large and demand is not equal to production, but, if the present rate of buying continues long, demand will at least approach supply. Whether this much desired condition will be attained is hard to predict. Electrolytic copper for first quarter delivery is quoted at 19.50c., New York, with Lake held at 19.75 to 20c., New York. In London electrolytic was quoted yesterday at £126 for spot, with futures at £128 per ton, which corresponds with 21.62c. in our market for the latter.

TIN

The sensation of the week has been the continued speculative advance in the London market with a leap of £17 15s. per ton on January 5 for spot Straits. This is probably a record advance for one day. The market there Monday was £365 15s. for spot Straits which eased off yesterday to £364 10s. In sympathy with the British market prices have advanced. Yesterday spot Straits, New York, was quoted at 63.50c., having been 63.75c. on Monday. These prices are largely nominal as the market presents very little activity. Dealers have been the buyers and they are reported to have bought up all cheap lots and thus to have brought the market up to the import cost. Importers who have sold have done so at figures considerably below the cost to import. As a result there are now scant offerings, the trading being between dealers with consumers holding off. A little business was done Monday on future shipment from the East at 64 to 64.25c., but now most dealers are asking 64.50c. and higher. The amalgamation on January 1 of the American Metal Co. and L. Vogelstein is regarded as a formidable

combination and as possibly an attempt to regain part of the trade lost during the War. Deliveries of tin into consumption during December were 6965 tons, of which 1665 tons came in at Pacific ports. In stocks and landing on December 31, there were 3438 tons. For 1919 the imports of tin were 35,104 tons as compared with 58,027 tons in 1918. Of the 1919 imports 26,225 tons came from the Straits, with 4700 tons from England. The advance in tin in London from November 5 to January 5, has been £88 15s. per ton for spot Straits.

LEAD

'Supplies insufficient to meet the large demand' is the keynote of the situation in the lead market. Spot lead is almost impossible to obtain which renders it very difficult to quote the market. Few if any producers have any. On Friday and Saturday, January 2 and 3, the American Smelting & Refining Co. raised its price ½c. per lb. each day, bringing its quotation to 8c., New York, or 7.75c., St. Louis. But the outside market has continued to keep in advance. This market may be nominally quoted at 8.50 to 8.75c., New York, or 8.25 to 8.50c., St. Louis, for prompt or early delivery with very little metal available. For February-March delivery 8.87½ to 9c. is the quotation firmly held. The present tight condition is predicted to continue through January and February after which relief is expected, due to present arrangements to increase production. In the two months ending January 5, spot lead in the London market has advanced £14 10s. and futures also £14 10s. per ton. There is some export inquiry in this market but how it is to be supplied is difficult to say.

ZINC

Foreign demand and market operations, particularly in London, continue to be the dominating influence in this market and prices continue to rise. Due to a sudden speculative advance in London on Monday and yesterday, prime Western became buoyant here and advanced from 9c., St. Louis, where it had held most of last week, to 9.50c., St. Louis, or 9.85c., New York. Foreign demand, particularly British, is most important and heavy. In the last two months ending January 5, the London zinc market has advanced £14 10s. for spot delivery and £16 per ton for futures. Domestic demand is still light and the position of producers seems technically excellent. Predictions are to the effect that American users of zinc are likely to pay high because they did not purchase when prices were much lower a few months ago.

ANTIMONY

The market is stronger but quiet at 9.75 to 9.87½c., duty paid, for wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is nominally quoted at 31.50 to 32.50c., New York, for wholesale lots for early delivery. The Aluminum Company of America is reported to have sold its entire 1920 output to regular customers at 32 to 33c. for virgin ingots. Some British metal is said to be available at concessions from these prices.

ORES

Tungsten: The market is quiet but cheerful over the prospects for the new year. Quotations are nominal at \$7 to \$15 per unit in 60% concentrate, depending on the grade of ore, but business is very light. Quotations for ferro-tungsten are still a matter of negotiation, though some reports place them at \$1 to \$1.15 per lb. of contained tungsten.

Manganese: Indian ore is offered at 65c. per unit and it is stated that American producers of ferro-manganese are likely to meet this price. Good ore is scarce both here and in England.

BASE-METAL mining is prospering, thanks to the better prices for lead and zinc. The European demand for lead is the cause of the recent rise in quotations, from 4.85 cents per pound last May to 8.75 in January of this year. Zinc was 6.31 last May and stands at 9 cents now. These are notable advances, and mean much to the miner.

IN this issue we publish the third of a series of articles on the Bunker Hill Enterprise, by the Editor. There will be twelve of these articles, which will cover the history of the Bunker Hill & Sullivan Mining & Concentrating Company, and describe the mining, milling, and smelting operations, as well as the geological and sociological phases of this highly interesting and unusually successful enterprise.

RECENT reports from the Transvaal indicate that the production of gold during 1919 amounted to \$160,000,000, a decrease from \$173,500,000 in 1918, and from \$192,200,000 in 1916. This compares with a production in the United States of \$58,500,000 during 1919, and \$68,500,000 in 1918. Australia shows a similar reduction. The record year of gold production for the world was 1915, in which period a total of \$470,000,000 was produced. Since 1915 the world output has steadily fallen; in 1916 it was \$454,000,000; in 1917, \$423,000,000; in 1918, \$372,000,000; and in 1919, probably \$350,000,000.

SHARES in Rand Mines, Ltd., are being offered in New York by advertisement in the newspapers. It is stated that dividends during the ten years preceding December 31, 1918, averaged \$4.62, at \$3.75 to the pound sterling, on each American share, which is equal to two and a half English shares. These so-called American shares are now offered at \$40 per share. Rand Mines is quoted in London at £33, which at \$3.75 is equivalent to \$13.96, so that 2½ shares are worth \$34.90. The offer seems unattractive. Moreover, the rate of dividend paid during 1918 represents a yield of less than 6% on the market quotation. This is far too little for a business that is decadent, even allowing for the assistance derived from the premium on gold. Those who read the 'Mining and Scientific Press' do not need to be told that the mines of the Rand show impoverishment in depth; therefore the purchase of shares in the companies operating them, especially a holding company like Rand Mines, Ltd., is not wise. The financial houses controlling the big min-

ing consolidations in South Africa have unloaded their stocks on the British public, which in the course of seven years lost \$203,931,610 by holding shares in the three principal consolidations, namely, Rand Mines, Crown Mines, and East Rand Proprietary. See our issue of June 8, 1918. We shall be surprised if the same people succeed in unloading their wasting assets upon the American public.

LAST YEAR scored several records. Ship building increased from 2,721,000 to 4,050,000 gross tons. Sales of Liberty bonds advanced from \$1,407,952,500 to \$2,658,400,000. The National Debt grew from 21 to 26 billion dollars. The population advanced to 107,600,000 from 106,050,000, not including overseas possessions. Wheat production increased from 921,438,000 bushels to 940,987,000. Wholesale prices rose from 207 to 222. Sales of stocks in New York increased from 144,118,469 to 319,337,000. The Stock Exchange had 152 'million-share' days, as against the previous record of 111 in 1906. Immigration increased from 110,618 to 249,000, but emigration kept pace, there having departed 258,000 as against 109,253 in 1918.

IMAGINATION is the very life of mining. The prospector, upon whom all mining depends, would make but a sorry success of his work without the power to visualize productive mines under the sand of the desert or under the brush of the wilderness. Many a famous mine would never have existed but for the vision of some man whose imagination led him far beyond his more solid brethren. This fact has made mining a fruitful field for the 'confidence' man, by whose exuberant prophecies the proverbial widow and orphan have been trapped. Gold mines of such fabulous wealth as to suggest the use of a wheelbarrow; copper mines that surely, as soon as a shaft or two has been sunk, and, possibly, a stope started, will rival the Anaconda; oilfields that contain subterranean lakes of oil; these are all too familiar to the readers of prospectuses, in some of which new mining districts of undoubted merit are so overdrawn, and facts and fantasy so intermingled, that it is indeed a canny speculator who can say that he has never been misled. We had thought that the vivid imaginations of these Munchausens of mining had probed every possible kind of ore deposit; yet in a reliable report that we have just received concerning a strange discovery in New Zealand, we once again see the vindication of an old

proverb. Kauri gum, which at present has a market value of about \$1000 per ton for use in varnishes, oils, and similar products, is formed from the sap of certain trees of the pine family that grow in New Zealand. The customary method of obtaining the gum has been by distillation of the wood of the parent trees, a process that, as it destroys timber of industrial value, has yielded a restricted output at high cost. At the northern end of North Island, near Auckland, there are large swamps in the peaty soil of which kauri gum is found in loose lumps. In swamps covering an area of 2100 acres, the gum has been found to exist to a depth of six feet, and experiments made by treating the soil by wet methods of concentration have yielded a recovery of 10%. This deposit, although known locally for some time, is just beginning to attract attention; in all probability therefore the methods of sampling have not been sufficiently reliable to warrant accurate estimates. Nevertheless, making allowances for the fact that dependable figures are not forthcoming as yet, the possibilities indicated are interesting. In another part of the swamp the peaty soil is being excavated and retorted for crude oil, a process not sufficiently different from our own oil-shale operations to incite comment. But the strangest part of this chronicle is yet to come. The gum in the soil has resulted from the disintegration of some prehistoric forest of kauri trees; indeed, excavations have established the fact that submerged under the surface of the swamp there are the remains of a forest of kauri trees, maintained in perfect preservation by the water. As the oldest Maoris have no recollection of a forest ever having existed on this part of the island, the disturbance that resulted in the submergence of the trees, before they had time to decay, must have occurred at least several generations ago. Prospectors have been removing these trees and working them into lumber, which has proved to be in good condition. So we have the extraordinary spectacle, even if only on a prospecting scale, of men mining useful timber from underground. We recall reading, some years ago, one of Frank Stockton's delightfully whimsical stories, in which the hero discovered the remnant of a glacier that had been buried and preserved for centuries, and so became possessed of an ice mine. Thus fact and fiction rub shoulders.

Herbert Hoover for President

The Presidency is the most important political office in the world, partly on account of the mere size and wealth of the United States, partly because this country is the acknowledged leader of the democratic idea in human government, but chiefly because no other potentate or president exercises so much personal influence upon the industrial progress of his own country. During recent years the executive branch of the Government, rightly or wrongly, has exercised a preponderant influence as against the legislative and judicial branches, with which it was intended, by the Constitution, to be equal and coordinate. It is a fact that the welfare of the American

people for the next four or five years depends more upon the choice of a President than upon the exercise of any other act of citizenship. We must select the right man. Who is he? Already the political atmosphere vibrates to the calls of candidates and their supporters. It appears to be the fashion not to wait for an invitation, but to come forward with a claim to nomination; several gentlemen have shied their hats into the ring and already are campaigning vociferously. Most of them can be ignored; their confidence in their eligibility for the supreme office in the Republic is not shared by many outside their own cliques. So far the names put forward by the professional politicians have evoked but little enthusiasm. A worn-out General, a backstairs diplomat, a Tory pedagogue, a hardy quadrennial, even the sadly battered present incumbent of the Executive Chair are among the more prominent presumptive nominees, but none of these is the man of the hour. The Presidency requires physical, as well as mental, strength. It is dangerous to elect any man not physically fit for the arduous duties of the office, which is one that makes extraordinary demands upon the vital powers. It is dangerous to have an invalid in the White House, for that means either the delegation of authority to subordinates or the performance of duty under conditions prejudicial to efficiency. The choice should fall upon a man in the prime of life, and it should recognize the problems that are insistent at this time. National economies asserts itself today unmistakably; the welfare of this country depends upon the effective and humane organization of industry; upon the far-sighted and sagacious adjustment of international economic relations. The issues inherited from the Civil War are dead; the tariff is no longer a live question; the old shibboleths are unpronounceable; we are facing a new era, which is the aftermath of a great war, in the course of which the economic factor became supreme. The pre-eminent exponent of that factor, nationally and internationally, is Herbert Hoover. First as the organizer of relief for American refugees, then as the savior of Belgium, then as the head of our Food Administration, and lastly as chief of the Relief Organization in Europe, he proved his intelligence, his sagacity, and his generosity to the utmost. Of the Government bureaus that played an important part in the national effort demanded by the War, one was conspicuously untouched by calumny and unscathed by criticism—that was the Food Administration. Mr. Hoover's work in this department proved itself extraordinarily effective; it received not only popular approval but enthusiastic support. Mr. Hoover showed himself highly competent as an executive; he won a firm hold upon the confidence of the people of this country, as of those in Europe, because he possessed the constructive imagination of an engineer. Talk about a business-man for President! The swivel-chairs of Washington were burdened with business-men, and a sad mess most of them made. The Presidency calls for something more than the qualities sufficient for success in business; it demands the trained mind and the disciplined imagination of the professional man, not of the academic type, but of the kind

that has had experience in leading and directing industrial energies. A knowledge of business, as such, is useful, of course, but it must be the business of right living as well as the business of easy money. The experience of commerce alone will not suffice. Mr. Hoover has the qualities required for the highest office. He is not an orator, and what a blessing it would be to have a President who was not forever speechifying! He lacks the facile insincerities of the politician, but he can express himself clearly when occasion arises. Democratic institutions are suffering from an excess of rhetorical confectionary; we are tired of the lawyer and his mending gab; it would be a relief to have an executive that would give less time to phrase-making and more to the business of government. That is a business of increasing difficulty, because the expansion of the suffrage and the interdependence of industries is creating new problems. During the term of the next President the relation of capital to labor, and of both of them to the public good, will be the supreme subject; we shall have to face our responsibilities to the world at large, with which the War has brought us into new and complex connections; we shall have to establish economy in our national exchequer and thereby correct the extravagance stimulated by war; we shall have to recognize the heterogeneity of our population and devise means for assimilating and educating the alien elements. The United States stands on the threshold of a great era; to make the most of it there is needed for President a man of intellectual honesty, an experienced administrator, a wise leader. Such a man is Herbert Hoover.

Prohibition

At this time the compulsory abstention from spirituous liquors is a subject of daily conversation. A sudden change in the habits of the average citizen, particularly when enforced against his will, is bound to cause irritation and evoke protest. In our last issue we published a 'kick' on the subject from one of our readers; it is the only 'kick', except the luxury tax, that he is permitted to enjoy in his now uninteresting potations. We are not without sympathy for him; the difference between us is that we reconcile ourselves to facts rather more readily, and we accept some of the drawbacks of democratic rule for the sake of the many benefits arising from this form of popular government. One after another the efforts to block the enactment of the prohibition law have been checkmated, until at last the fateful 16th of January has arrived. The fight for liberty to drink alcoholic beverages is not ended. There remain other attempts to circumvent the permanent establishment of prohibition. Some of them are foolish. For example, the 'New York Times' quotes a declaration that is being signed all over the country; it reads thus: "Believing that the Constitutional Amendment passed by Congress and ratified by a majority of the States is an infringement upon my personal liberties, I hereby pledge myself to vote against any candidate for public office, regardless of party affili-

ations, who favors its enforcement." Our New York contemporary says: "The pledge is certainly too sweeping, and in form and language is of bad example." It is worse than that, it is childish. As grown men under a system of representative government, we must accept quietly and good temperedly the decision of the majority. That it is a real majority, there is no doubt. It remains, however, to take warning, first of all, of the insidious effectiveness of persistent propaganda, and to be on our guard in the future against such changes in our laws or in the Constitution as may be brought about in a similar way. It is better to be sure than sorry. Prohibition is a standing example of the fact that if you say the same thing often enough it will be believed by the average man. Not many think for themselves; if bombarded by the thoughts of others, they surrender. Again, the manner in which prohibition was rushed into law calls for serious objection. The time required to elapse between the ratification of a Constitutional Amendment and the date on which it goes into effect is supposed to provide an opportunity for adjustment to the new conditions imposed by such a change in our fundamental law. In the case of national prohibition, this salutary provision was impaired by war-time prohibition, which, by coming into force during the period of grace, to all intents and purposes antedated the operation of the 18th amendment to the Constitution. The President, wisely and properly, vetoed war-time prohibition as soon as the Expeditionary Force had been demobilized; in doing so, he recognized the facts of the case. His veto was set aside by well-meaning fanatics. The enforcement of war-time prohibition nearly eight months after the signing of the Armistice left no interval between the incidence of that enactment and the imposition of perpetual prohibition by means of the Constitutional Amendment. This savors too much of 'railroading' tactics, which are repugnant to those who, most properly, view with anxiety the overthrow of such basic provisions in our law as are meant to protect the people from any curtailment of their liberties without deliberation and the rigid observance of the safeguards created for that very purpose. The 18th amendment was 'rushed'; of that there is no doubt. For example, many States have a proviso in their own constitution giving their people the right to a referendum. Ohio exercised that right, and reversed the vote of its legislature. Since the date, January 16, was determined by the day when the last of the 36 necessary States ratified the amendment, it would appear as if the defection of Ohio creates a flaw in the legality of the amendment. Moreover, the unseemly haste to bring national prohibition into force has had the effect of doing injury to persons engaged in an industry heretofore recognized as legitimate. The culture of the grape, the production of wine, the manufacture of spirituous liquors generally constituted forms of industrial activity and financial investment that the Federal government and many of the States had approved, and had even fostered. In common justice the men that had placed their money in this business and those that depended upon it for a livelihood

should have been given a fair chance to make the severe adjustments entailed by the new law. The time covered by war-time prohibition should have been treated as 'time out', to use a sporting term, when determining the date at which perpetual prohibition should begin under the 18th amendment; and, of course, the preservation of the rights of the citizen, to conserve which this republic was founded, called for such a ratification by the necessary 36 States as left no suggestion of a flaw. The pros and cons of prohibition may be the subject of discussion, but there should be no room for debate concerning the observance of the basic principles upon which representative government is founded. There are things more vital than either the permission or the forbiddance to drink. One of them is a strict regard for the constitutional rights of the citizen; another is the acceptance of the vote of the majority. We think that although prohibition was brought about by methods and means open to serious criticism, and although the history of the entire movement should serve as a warning against the repetition of such a performance, yet it does express the will of the majority of the people in our State and in the United States, and therefore it should be accepted good-temperedly. We are sorry for our elder brethren whose habits of a lifetime—habits by no means bad—have suffered a ruthless break; we envy the undemocratic advantage of the rich in being able to store large stocks of liquor in their own cellars, while the rest of us must go 'dry'; we are glad to have had our share of good burgundy before the question of abstinence from wine became irretrievably involved with that of drinking bad whiskey in saloons; we congratulate the wives of men who formerly spent their wages in getting drunk; and, most of all, we shake the hand of the mothers who now can thank Heaven that their sons will escape the temptation that has ruined many promising careers. Selah.

System in Mining

The latest report of the North Butte Mining Company ascribes a remarkable reduction in the cost of producing copper during the past year to the development of systematized methods for handling labor, for distributing supplies, and for performing each phase of underground operations in accordance with standard plans. Other companies likewise have effected economies by a similar systematization of effort. Broadly speaking, the efficiency of mining operations, like that of any other industry, depends upon two factors, namely, skillful management and willing employees. To be precise, the maintenance of an efficient personnel is a function of administration, but as a result of unprecedented conditions brought about by the War, and the accompanying unrest among working-men, the labor question has become a highly important and complex problem in itself. Assuming that this has been solved as well as may be under a particular set of conditions, there is still an immense field for betterment in the scheme of organization; in the selection of material and equipment; in the system for

distributing this material and equipment; and in the method of performing each detail of the mine-work; all of which can be considered separately from the supply of men to carry on the work as planned. If there is no incentive sufficiently strong to induce the miner to work with at least some diligence, comparatively little will be accomplished under any circumstances; on the other hand, if the employees are inclined to be fair and work reasonably hard during the full period of their shift, a remarkable improvement in results can be obtained in most mines by the application of a system suited to the special conditions. When the manager of a mine considers the fact that the output of such a comparatively simple plant as a machine-shop in an automobile factory has been increased as much as tenfold by the introduction of plans, schedules, and standard practice, he must see possibilities in the adaptation of the same ideas to his own business. The objection has been raised that conditions characteristic of mine operations make the adoption of 'time study' and 'dispatch' methods impracticable, but it seems rather as if these peculiarities have simply served to conceal extraordinary waste of material, of effort, and of time, which are preventable to a large extent. It is true unfortunately that so-called 'efficiency' work generally arouses opposition among miners and even foremen, who are inclined to resent the idea of having 'pencil-men' plan their work for them. For example, consider the ordinary round of holes drilled in advancing a drift. The experienced miner confidently believes that he can go into the heading, and, by sizing-up the various seams and cracks in the face, determine the number, direction, and position of the holes required to break the next round most effectually. As a matter of fact, it is highly probable that his round will not meet the requirements more than 60% as well as a standard round that has been devised intelligently by an engineer specially qualified for such work. One large mining company calculated an actual yearly saving of \$240,000 in its powder bill, as a result of the scientific use of clay tamping. It was necessary, of course, to determine just what amount of tamping could be advantageously used in each hole of a standard round, without in any degree lessening the effectiveness of the blast, for there is no economy in saving powder at the expense of the proper breaking of the ground. The average miner if left alone is prone to gauge the quantity of powder simply by the capacity of the drill-hole. In some mines careful investigation showed that from 25 to 50% of the average miner's time was devoted to assembling or waiting for tools, equipment, timber, pipe, and the like. A large proportion of this waste of time has been avoided by substituting systematic distribution for haphazard ways. These are but a few of dozens of illustrations that might be given of the improvements that actually have been brought about by the application of efficiency, which, when scorned of its obscuring nomenclature, is nothing more than an organized and painstaking use of common sense in getting a given result with a minimum expenditure of time, money, and effort.

The Bunker Hill Enterprise III

Discovery of the Lode and the First Operations at the Mine

By T. A. RICKARD

The facts concerning the discovery of a great mine are usually obscured by a glowing tissue of fiction, which is readily accepted because it appeals to the love of the romantic and the fabulous. Not uncommonly the truth is stranger than the fiction and a real romance is smothered by sublimated gossip. The story of the Bunker Hill is no exception; but, fortunately, in this case the facts can be extricated by a careful reading of the various statements of those who participated in the event.

We have seen how mining in Idaho began with the

tions that Kellogg might make in the course of his prospecting trip, for which they provided him with a 'burro', or donkey, and \$18.75 worth of provisions. These consisted of 15 lb. of flour, 7 lb. of bacon, 2 lb. of coffee, 8 lb. of beans, 1 lb. of dried apples, \$1 worth of sugar, one pair of \$2.75 shoes, and a half dozen of printed location notices. He was to prospect on the south fork of the Coeur d'Alene river for gold, because it was in gold mining that they were interested and that Kellogg had the necessary experience. By the 27th day of the month Kellogg had consumed the supplies furnished by Cooper and

MAP OF THE COEUR D'ALENE

successful digging for gold in the gravel of the mountain valleys. Murray was one of the centres of such productive operations. The firm of Cooper & Peck operated a store of general merchandise in that town. During the summer of 1885, John T. Cooper and Origin O. Peck grubstaked a prospector named Noah S. Kellogg. In frontier communities 'grubstaking' is a recognized form of mining speculation; it consists in supplying a prospector with food and tools, in return for which he undertakes to give his backer a half-interest in any mineral discovery he may make. Such was the deal that Kellogg made with Cooper and Peck on August 1, 1885. They were to receive a quarter interest each in any loca-

tion, besides other provisions he had purchased elsewhere on his own account. So he testified in court at a later date. His prospecting had been almost a failure, for during the month he had only located the 'Mary A.' and 'Kellogg' claims on Elk creek, and neither of these proved to have any value at that time. He returned to Murray with a few samples of what appeared to be iron-stone, of which Cooper and Peck thought less than nothing. On August 29 he returned, at the request of his backers, to search for a vein showing free gold, such as the veins that had made men rich in the hills around Murray. He was told not to bother about 'iron rock', but to go

¹This is the first creek east of Milo gulch; see map.

again to Big creek, where he had previously picked up some pieces of quartz that looked promising. For this trip Cooper and Peck provided him with 19 lb. of flour, 8 lb. of bacon, 8 lb. of beans, 4 lb. of sugar, 4 lb. of coffee, one coffee-pot, one camp-kettle, one pair of shoes, and two location notices. This time he remained in the hills until the 12th of September, by which date he had exhausted his stock of food. Evidently he had neither time nor inclination to supplement his 'grub' with fish or game. On this second return to Murray he told Cooper and Peck that he had failed to discover any gold-bearing quartz; he gave them copies of the location notices of the 'Mary A.' and 'Kellogg' claims, to which he had added their names as owners. He returned the donkey, which, as we shall see, played a prominent part in the subsequent story. Kellogg claimed that he then and there terminated his 'grubstake', or prospecting agreement, which meant that Cooper and Peck had no further interest in his actions or in any discoveries he might make subsequently.

This explanation of his actions as a prospector was disputed when subsequently the grubstake became the subject of an important lawsuit.

Now we come to other actors in this frontier drama. Philip O'Rourke was a miner of considerably wider experience. He had been to Leadville, in Colorado, and knew something about the mining of silver-lead ores. Jacob Goetz, commonly known as 'Dutch Jake', was a mining adventurer, of genial nature and many resources; he and his partner Harry Baer had a grubstake agreement with O'Rourke. To O'Rourke and Goetz came Kellogg soon after his second* prospecting trip in the hills above the south fork of the Coeur d'Alene river. He showed them the pieces of 'iron rock'. Goetz testifies that Cooper and Peck had taken similar samples to John M. Burke, a man with a local reputation for knowing ores, and he had said that it was 'smelting ore', which had disgusted Kellogg's backers, who, as recorded already, only wanted 'free-milling' gold ore. When, however, Kellogg's samples were shown to Phil O'Rourke, he recognized them as coming from the cap of a lead lode. The samples reminded him of the oxidized ore he had mined at Leadville; the 'iron rock' excited his interest; therefore he suggested to Goetz that they join Kellogg in staking the ground. Goetz had horses and provisions, both of which he turned over to O'Rourke and Kellogg, who started forthwith down the valley. Mr. Goetz says² that Kellogg notified Cooper and Peck at this time, which he does not specify, that he had 'quit the grubstake deal with them', but the evidence laid before the jury showed that the notification to Cooper and Peck was given on September 13.

Kellogg took O'Rourke first to Big creek, east of Elk

creek, where he showed him the ironstone outcrops, some of which later became identified with the Yankee Boy, Southern Cross, and other productive silver-lead mines. Then the two prospectors proceeded a short distance farther down the south fork of the Coeur d'Alene river until they came to Milo creek, which is next to Elk creek. Turning up Milo creek, they went to the Bunker Hill outcrop, which crosses the gulch from side to side, as can be seen to this day. Who found the lode and how he found it are questions that cannot be answered confidently despite a study of the testimony given in the subsequent lawsuit.

Mr. Goetz, whom I interviewed at Spokane, told me that O'Rourke was the discoverer. He found 'float', or loose fragments of oxidized ore, at the bottom of the mountain-side near the place where the first mill was built later. At a point 400 to 500 ft. above the creek on the west side he struck his pick into an irony outcrop and broke away pieces that showed the glint of galena. He traced this ore for a distance of 500 ft. up the slope. Having done this, he sat down on the outcrop dumbfounded by the realization of his discovery, which seemed to him 'the biggest thing in the world'. It must be remembered that O'Rourke's experience at Leadville had given wings to his imagination. He was too excited to make a location, but he did insert a stake in the ground before he descended the hillside in search of Kellogg. The day was September 9, 1885. Next day O'Rourke located the 'Bunker Hill' claim with Kellogg as witness. Goetz tells the story thus:

"Kellogg took O'Rourke down to Big creek, on the South Fork, and pointed out the big iron capping that covered the ledges. Moving down the river, they came to Milo creek, where Kellogg now stands. There they lost a pack-horse, and while old man Kellogg went in search of it up Elk gulch, Phil started the hunt up Milo gulch. At the head of the creek he found some galena float, and though it was dreadful hard work to get through the brush and fallen timber he climbed up the hill about 500 feet and there he stumbled upon the great Bunker Hill ledge, sticking right up out of the ground. There was nothing in sight but glittering galena, and O'Rourke knew he had found the greatest thing ever discovered in the Northwest. He was so excited that he sat down half an hour before he knew what to do. Finally he rushed back to Kellogg, who was in camp at the mouth of the gulch, and after supper they spent the time planning how to locate their find. Phil was so excited that he had forgotten to put up any posts. That night he wrote out the location notice, and called the claim the 'Bunker Hill', after the battle of the Revolution. But he decided it would be best to have Kellogg sign the notice as locator, for Phil had a lot of friends who loaned him money, and they might try to claim an interest if it was staked in his name.

"Next morning they started up the gulch about two miles to make the location, but their cayuses had strayed away. As luck would have it, they found the old white burro that Cooper & Peck had turned over to Kellogg as

*Whether it was the first or the second trip is a critical question; I am giving the story now as told by Goetz and others, and as generally accepted. Later, I shall revise it in the light of further evidence.

²'Dutch Jake's Account', Spokane's Home Builders, November, 1910.

a part of his grubstake. The burros were packed away when Kellogg was there first. They caught the beast, and loading their picks and grub on it, they went up the gulch to the Bunker Hill lode. Then Kellogg happened to think that may be he'd better not appear as locator, for Cooper & Peck might claim an interest on account of his first grubstake. So they threw away the location notice, with Kellogg as locator, and wrote a new one with O'Rourke as the locator and Kellogg as witness."

On their return to Murray they reported to Goetz, and a consultation ensued. O'Rourke was burdened by gambling debts; among others to whom he owed money was Cornelius Sullivan, another Irishman, known to his

arrived so, and Sullivan relocated the extension, calling it the 'Sullivan' claim. That was on October 2.

Another account of the discovery appears in an autobiographical sketch by James F. Wardner, a frontiersman and mining adventurer. He says that "to Kellogg's jack's trick of losing himself when most needed, however, and to his alleged sagacity in knowing a pay-shoot when he saw it, is due the discovery of the great mine; and in Dutch Jake's famous resort in Spokane there is a lifelike oil painting of the jackass standing

JIM WARDNER

JACOB GOETZ

friends as 'Con'. So it was decided to take him into the deal. That night Goetz and Sullivan started for the scene of the discovery, but they missed their way and lost time. Meanwhile Peck heard about it and found his way thither; by chance he picked up the location notice that Kellogg had discarded and learned through the talk of the others that his burro had been used by Kellogg and O'Rourke. Whereupon Peck, on his return to Murray, on September 26, started to bring suit for Cooper & Peck against the locators, claiming a half-interest on the basis of the grubstake agreement with Kellogg. Peck failed to locate the extension of the 'Bunker Hill', because "O'Rourke had put up some fictitious posts to hold the ground", so says Goetz. Therefore, as soon as Goetz

upon the apex of the Bunker Hill and gazing abstractedly across the canyon to the glimmering outcroppings of the Sullivan".

It will be noted that to the poor donkey, like Balaam's ass, is attributed more sagacity than to his master. Sullivan is reported, by Wardner, as having said to him:

"Well, Jim, we don't know how you come to strike our trail, but we've got something here worth a long journey to see. Look up there!" And, as he spoke, Sullivan pointed to the right-hand slope of the canyon from the camp, just as the sun had risen to a point where its morning rays fell full upon the side of the mountain.

What seemed to be a vast sheet of new tin dazzled the eyes. I had never seen such a sight before—nor since.

'Galena,' I said.

'That's what,' replied O'Rourke.'

"His may be picturesque, but it is pure fiction. Wardner proceeds to record Kellogg's statement:

"It was this a-way," began Mr. Kellogg; 'the damned jack shook us one night at the mouth of the creek, and the next morning we started out to find him. His tracks were plain, and now and then we found great wads of his hair where he had climbed over the down timber and scraped his sides against the logs. How under the heavens the little devil managed to get through that place I can't tell; but after we got into the canyon proper his trail was easy. Looking across the creek we saw the jack standing upon the side of the hill, and apparently gazing intently across the canyon at some object which attracted his attention. We went up the slope after him, expecting that, as usual, he would give us a hard chase; but he never moved as we approached. His ears were set forward, his eyes were fixed upon some object, and he seemed wholly absorbed. Reaching his side, we were astounded to find the jackass standing upon a great outcropping of mineralized vein-matter and looking in apparent amazement at the marvelous ore-shoot across the canyon, which then, as you now see it, was reflecting the sun's rays like a mirror. Jack fairly heaved a sigh of relief as he heard our vigorous comments. We lost no time in making our locations, and where the jack stood we called it the Bunker Hill, and the big shoot we named the Sullivan in honor of Con.'"

This also is a cheerful fabrication. Kellogg is not likely to have said anything of the kind at the time recorded, for it was not true; later he may have started to adorn his tale, or, what is more likely, Wardner may have embellished it with the mention of the glittering galena and the donkey's rhapsody. In the first place, neither Wardner nor Kellogg nor the gentle jackass ever saw a glistening mass of galena outcropping there or anywhere else in nature. Galena oxidizes when exposed to the weather and loses its bright lustre, becoming the dull sulphate or the equally dull carbonate, which usually is colored red by the oxidation of a small proportion of associated iron pyrite. The outcrops of lead lodes consist commonly of dark-red ironstone with gray spots of anglesite (the sulphate) or cerussite (the carbonate) in the midst of which small unoxidized remnants of galena may survive. Portions of the Bunker Hill outcrop can still be seen near the place of discovery; they consist of iron-stained quartzite with specks of galena. The talk of a glittering mass of silvery mineral sticking out of the mountain-side so brilliantly as to mesmerize the ass, and others not much wiser, is pure moonshine. What did happen probably is that the donkey, intelligent enough to find fodder for himself, strayed through the pine forest above the creek toward the outcrop, because near it there was a

bit of open space covered with bunch-grass, as can be seen to this day.

However, the story of the burro is now fixed in local history and even in the local concert-halls jingles of an earlier day:

"When you talk about the *Coeur d'Alenes*

And all their wealth unfold,

Don't fail to mention Kellogg's jack,

Who did the wealth unfold."

Jim Wardner, in his autobiography, says that Judge Norman Buck, of the District Court of Idaho, who decided the celebrated case between Cooper & Peck and the prospectors who located the Bunker Hill, recognized the agency of the ass, and that his decision was as follows:

"From the evidence of the witnesses, this Court is of the opinion that the Bunker Hill mine was discovered by the jackass, Phil O'Rourke, and N. S. Kellogg; and as the jackass is the property of the plaintiffs, Cooper & Peck, they are entitled to a half-interest in the Bunker Hill and a quarter interest in the Sullivan claims."

By courtesy of the Clerk of the Supreme Court at Boise, I have been enabled to read a copy of the proceedings in this case. This is what Judge Buck, on June 12, 1886, gave as his opinion: "That the plaintiffs are entitled to a decree as against N. S. Kellogg and Phil O'Rourke for an undivided fourth interest of in and to the Bunker Hill mining claim, as described in the complaint as they held the same September 10, 1885, and all interest acquired since said date in and to said claim and judgment for costs against defendants."

The plaintiffs were John T. Cooper and Origin O. Peck. The defendants were N. S. Kellogg, Phil O'Rourke, Cornelius Sullivan, and Jacob Goetz. The questions submitted to the jury by the defence were answered in favor of the defendants, sustaining their contentions, whereupon the defendants asked the Court for a decree stating that the plaintiffs had no cause for action and assessing the costs of the suit against them. The judge, however, denied the motion and set aside the findings of the jury. Instead, he rendered the decree as quoted above.

It is evident that Jim Wardner made free with the Court's "conclusions of law" in order to give a touch of verisimilitude to his picturesque yarn. Judge Buck did not mention the donkey in his findings; he found that on September 10, when Kellogg and O'Rourke jointly located the 'Bunker Hill' claim, Kellogg was still "under a contract with the plaintiffs whereby and under which the said plaintiffs were entitled to the undivided one half interest in and to all mining property located or acquired by said Kellogg during the term of said contract," which did not expire until September 13, the day on which Kellogg gave notice to that effect.

This disposes of the main question, namely, that of discovery; but the lawsuit involved the title to other claims, located subsequently to the 'Bunker Hill'. Cooper and Peck alleged that Kellogg discovered the lode prior to August 29 and located five claims called the

"Goetz says that this claim was named "In honor of John L. Sullivan, the pugilist". It will be noted that he mentions "a pack-horse" and "cayuses", as well as the donkey.

'Bunker Hill No. 1', 'Bunker Hill No. 2', 'Fraction', 'Accident', and 'Richmond'; and that, in order to evade his liability under the grubstake, he took O'Rourke with him to Milo creek on September 10, upon which date they took down these location notices and substituted new ones. First they located the 'Bunker Hill' claim in their joint names and then on the same day they re-located it in the name of O'Rourke alone. The rest of the locating, it was alleged, was postponed until September 15, that is, until after the grubstake had been terminated form-

posted a notice claiming certain grounds as the Accident lode in his own name, but allege the truth to be that said notice was posted on the 16th day of September, 1885, and long after the termination of said agreement between plaintiffs and said Kellogg.

The issues of fact were submitted to a jury, which, *inter alia*, decided as follows:

1. That the grubstake terminated on September 13.
2. That the supplies furnished by Cooper & Peck were exhausted by Kellogg on September 9.

3. That Kellogg did not discover "any rock in place bearing gold, silver, or other mineral upon any of the lodes described in the complaint."

4. That Kellogg assisted O'Rourke in locating the 'Accident' claim and in measuring the 'Bunker Hill'.

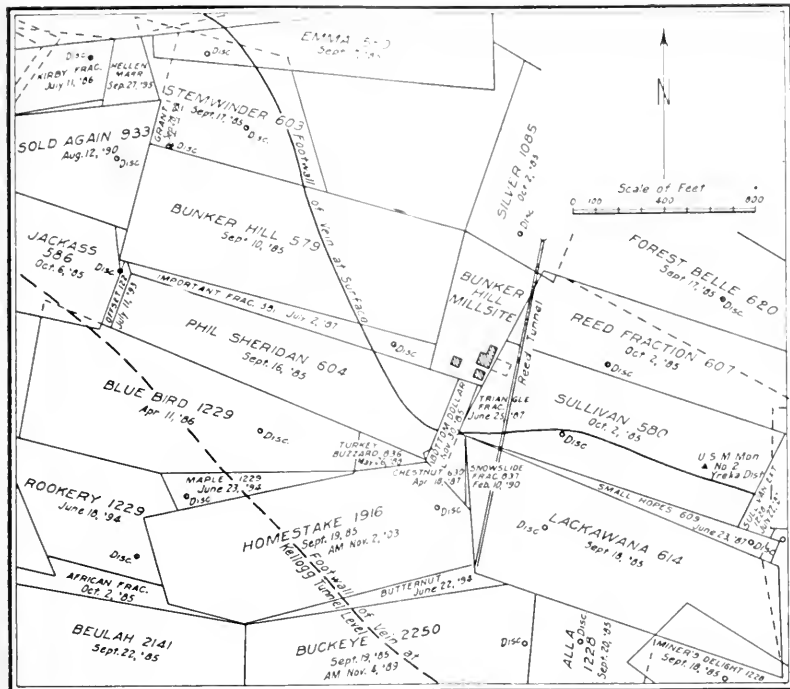

5. That O'Rourke located the 'Bunker Hill' on September 10, the 'Richmond' on September 18, and the 'Accident' on or about September 19.

6. That O'Rourke received no information from Kellogg "which led him to such locations".

7. That O'Rourke took down the 'Accident' notice posted by Kellogg on September 16, and that he requested Sullivan and Goetz to re-locate it on October 2.

8. That a "consideration for assisting in discovering and developing this claim" was paid by Sullivan and Goetz to O'Rourke.

As to the 'Accident' location, the Court decided: "That the defendant N. S. Kellogg knew of the existence of the Accident or Sullivan lode claim and the lode therein prior to the 13th day of September, A.D. 1885, and having such knowledge withheld the same from the plaintiffs at the time he claims to have given notice of the termination of the grubstake contract, and immediately thereafter, to wit, on the 16th day of September, 1885, he went upon the ground and posted a notice of location thereof, in his own name, and under and by virtue of posting said notice he then and ever since has been the owner of an interest in such location, and that the claim upon which said notice was posted was fully and legally perfected and title acquired thereto by defendant Kellogg."

EARLIEST LOCATIONS COVERING THE BUNKER HILL MINE

ally by Kellogg. On that day the 'Accident' location notice was pulled down and a new one, in which O'Rourke's name replaced Kellogg's, was substituted. Next day the same was done to the 'Richmond', and on September 20 the 'Fraction' likewise was credited to O'Rourke. This did not end the changes; on October 2 the 'Accident' location notice, it is alleged by plaintiffs, was torn down and the claim re-located as the 'Sullivan' in the names of Sullivan and Goetz.

The defendants entered a formal denial to these allegations; they stated that "on the 13th day of September, 1885, the defendant Kellogg returned said jackass to the plaintiffs and notified them that he would no longer prospect for or in behalf of the plaintiffs, or for the benefit of himself and plaintiffs, and thereupon terminated the said prospecting co-partnership".

In regard to the locating, they denied the supposed earlier locations by Kellogg, but they admitted that he

The dates of location as given in the various accounts of the discovery are discrepant; for instance, Mr. Goetz says that the 'Sullivan claim' "was staked September 10, 1885, just ten days after the Bunker Hill was staked". The 'Bunker Hill' was located on September 10 and the 'Sullivan' on October 2. The correct dates of the surviving locations, as recorded in the county office, appear on the accompanying map.

It remains to disentangle the truth from these contradictory versions. Wardner gives no dates. He was a friend of the locators and became interested with them in the Bunker Hill discovery, so, of course, he repeated their version of the affair, plus his own embellishments. Goetz had grubstaked O'Rourke and participated in the venture, besides being himself a locator of one of the later claims; therefore he told a story that would defeat the demands made by Cooper & Peck on the basis of their grubstake agreement with Kellogg.

I have studied the statements made by Cooper, Kellogg, O'Rourke, and other witnesses in the course of the trial. Their testimony is full of contradictions, and obviously contains many falsehoods. On inquiry among those who knew the actors in this frontier drama, I find that all the prospectors were 'broke', chronically. Kellogg was slow-witted and lazy. O'Rourke was not a man of much mining experience, although he had been to Leadville; he was fonder of whiskey than of work. Con. Sullivan was "a good sort", but no miner. 'Dutch Jake' and his partner Harry Baer were "the knowing ones of the bunch", meaning not that they were wise in mining, but shrewd in business. Cooper and Peck were respectable storekeepers; the senior partner was addressed as "Dr." Cooper. His testimony is that of a fairly educated man; it is not rambling, like that of the others. The jury's findings need not be taken too seriously as against the judge's decision, for the twelve 'peers' would be in sympathy with the 'boys' and would regard discrepancies of statement as of no great moment; according to their code, it would be as proper for a miner to forswear himself in order to help a 'pal' as for a 'real' gentleman to perjure himself in an effort to protect a lady's reputation. I have not the slightest doubt that Judge Buck's decision was just; in short, it appears to me that the evidence can only be harmonized by concluding that Kellogg and O'Rourke 'put up a game' to circumvent the grubstake as soon as they knew a valuable discovery had been made.

In the account written by Mr. Goetz, it will be noted, he says that "the burro had wandered away when Kellogg was there first", although just before he has been explaining how O'Rourke alone had discovered the lode and was then taking Kellogg with him, for the first time, to show him the outcrop and help him in making a location. Early in August, Cooper provided Kellogg with six location blanks; he used two of them on the 'Kellogg' and 'Mary A.' claims; what did he do with the other four? Did he use them to make locations in Milo gulch and did he pull them down afterward, when he decided, with O'Rourke's aid, to avoid his obligations to Cooper &

Peck, by re-locating the claims after he had given notice of the termination of the grubstake?

It is difficult to disentangle the talk about "iron rock" and Cooper's alleged disclaimer of interest in anything but gold-bearing quartz. I venture to interpret the evidence as follows: Kellogg, when he returned to Murray, on August 28, showed Cooper some pieces of ironstone broken from an outcrop on Elk creek. These probably came from what is now known as the Iuka outcrop on the Alhambra property. He appeared to have brought back with him some other samples of ironstone (from Milo gulch?) that contained a little galena; he may have shown these to Cooper, and Cooper may have disclaimed them also; but when he showed them to O'Rourke, that son of Erin knew enough—thanks to his sojourn at Leadville—to recognize the lead ore. He asked Kellogg where he had found it and arranged to go back with him. Cooper testified that he suggested sending Peck with Kellogg to see his locations, but Kellogg replied that there was no necessity for doing so. Kellogg himself testified that when he reached Myrtle on his way out from Murray, on August 29, he was hailed by O'Rourke, who offered to go with him. O'Rourke said that Kellogg showed him some "iron rock" from the South Fork country and asked him what he thought about it. He learned that Kellogg was "going back" next day, so he proceeded to collect sundry necessary supplies and "waited" at Myrtle "until Kellogg came along". They proceeded to the South Fork. Kellogg went to Big creek and he (O'Rourke) went to Milo gulch, where, on the fourth of September, not the ninth as Mr. Goetz says, he discovered the Bunker Hill outcrop. He "got a piece of galena that day; it was coated with iron, broke it open and found galena inside"; later he found some more similar float by ascending the hillside. At the end of the day he went to the mouth of the gulch—he says—slept there, and next day "went back to camp on Elk creek, and wrote a note to Kellogg", who turned up four days later, on September 9, by which time O'Rourke had broken the outcrop in several places and determined the strike of the lode. "He [Kellogg] had got back from Big creek," testifies O'Rourke, who says that he located the 'Bunker Hill' on the 10th, adding that Kellogg was not present when he wrote the notice, on which his name appeared as 'witness'. That seems unlikely. Together they returned to Murray next day and showed specimens of the ore to their friends, but not to either Cooper or Peck.

The stories told by Kellogg and O'Rourke are fishy. Under cross-examination the latter acknowledged that "the first notice" he posted on the 'Bunker Hill' was "probably blown off the post in the first instance". He testified: "Don't know the exact date when it was done, for was not very particular about it until I found it was in the hands of plaintiffs, wrote another notice describing the ground exactly the same to the best of my opinion, posted and recorded it."

It is not worth while to go into further detail. The Judge that tried the case had all the evidence before him,

and the faces of the witnesses as well, he decided that the discovery was made by Kellogg while still bound by his grubstake agreement with Cooper & Peck. It appears to me most probable that the Bunker Hill lode was discovered by Noah Kellogg on or about August 26, 1885, and that he was led to it by his search for the donkey, who, more energetic than his master, climbed the hillside in search of fodder, and found a patch of bunch-grass in a small clearing close to the outcrop, where, on account of the mineralization, the ground was comparatively free from trees. That much of the story may have been true. In the subsequent quarrel, the burro served as a herring drawn across the trail of the prospectors. Perhaps "herring" is inappropriate; then let us say that he

and there raise the necessary capital, if they would give him an option. The talk began with one bottle of whiskey and was clinched with a second. As Wardner records, "pledges over the last of the whiskey were made", and he went then to the mine to collect the samples. Before starting he posted a notice locating 10,000 inches of water in the Coeur d'Alene river. These rights, he says, he sold later for \$50,000. By the way, apropos not of the water but the whiskey, what a difference there would have been in the stories of Western mining discovery if prohibition had been antedated 50 years! On reaching Spokane, Wardner had his samples assayed and was delighted to find that they ran high in silver, as well as lead. He proceeded to San Francisco

THE CELEBRATED DONKEY STANDING IN THE MAIN STREET OF WARDNER
The star marks the position of the mine

served as the aniseed bag for the hunt that followed. Certainly his alleged part in the actual discovery of the lode is mostly fiction; yet it is amusing to see how he remained for 35 years the hero of the tale, or a hero with a tail. As to the "glittering galena" by which he was hypnotized, that resembles the "red" lobsters that an eater rather than a fisher of lobsters said that he had seen deep down in the sea-water. The outcrop of silver-white galena recalls the proverb which says that there may be such things as volant non-ruminating artiodactyles, but at the same time declares them to be very unlikely birds.

The case of Cooper & Peck against the locators was appealed, but, in the meantime, Jim Wardner joined hands with the locators and started to raise the working capital necessary to develop a mine. According to his own description of his doings at that time, he explained to Kellogg, O'Rourke, Sullivan, and Goetz that their lead ore was no good unless it was worked on a big scale, which involved the building of roads and a mill. He offered to take samples of the ore with him to Spokane

in order to see the Selby Smelting Co. This company was only too glad to buy the ore at a price that left a good margin of profit to the owners of the Bunker Hill. Wardner returned to the mine and contracted to buy 25,000 tons of ore, he to advance the owners \$5 per ton and they to produce not less than 20 tons daily. About 800 tons of ore was taken out of the orebody in the Sullivan claim; when this was exhausted it became apparent that, although the lode was wide, only stringers of galena continued in depth. Wardner received \$115 gross per ton on the 800 tons and felt confident that more ore could be found. Then followed an anxious time while a tunnel, or adit, was run into the lode at a lower level. Wardner had abandoned hope and was on his way to Spokane when he was recalled by the foreman, Brady, who came down the trail shouting excitedly to him that they had "struck it big in the main tunnel". He had just met Tom Erwin and was having a drink of whiskey (again whiskey at the critical moment!), so he took another stiff drink before going to the mine, where he

found that "the boys had broken into a solid shoot [he spells it "chute"] of galena for the full size of the drift". "It was a wonderful sight," he says. "After going in on it for a little way, I started a cross-cut, and the shoot proved to be 36 ft. wide. Then we drove the drift night and day. I had 40 men at work, and after mining 100 ft. on the vein we cross-cut again. It was still 36 ft. strong." He sampled the ore and found that "while the ore-body was marvelous in its dimensions, the values were cut down to a concentrating proposition". If it was "solid galena", it would not need to be, nor could it be, concentrated. Of course, this stuff of Wardner's makes interesting reading, but it is quite evident that he does not allow himself to be hampered by facts. However, if what he says did not actually happen, it might have happened and something like it did happen. To the reader it will give something of the atmosphere of whiskey, resource, and adventure that surrounded these pioneers of industry.

Wardner, so he himself says, went to Spokane, Portland, and San Francisco to raise money, presumably to build a concentrating mill. He says that he made an attempt to induce capital to take hold of what he believed to be "one of the most desirable investments ever offered". As if a lode containing masses of silver-lead ore of uncertain persistence in the mountains at a distance of 60 miles from the nearest railway could be called "one of the most desirable investments ever offered". However, that was a miner's optimism, and in this case it happened to prove true in the end!

At a loss what to do, Wardner remembered "an active young fellow named Austin, since then inventor of the pyritic smelting process". This refers to my friend William Lawrence Austin, an accomplished metallurgist and the introducer, as Wardner says, of the pyritic smelting process—in 1892, if I remember correctly. Wardner went to Toston, in Montana, where Austin was then, in 1886, running a smelter. Austin examined the samples of ore from the Bunker Hill and made some assays, after which he assured Wardner that if his statements were true (a wise proviso), he had "the biggest concentrating proposition in the country". Austin advised Wardner to go to Helena and see Governor Sam Hauser.

Mr. Austin tells me that he recalls the visit from Wardner. He appeared unexpectedly one day, dragging a bag containing lumps of fine-grained galena. He wanted to know what was the best way to treat an ore of that character. "It was a clear case of smelting and I told him so," writes Mr. Austin. "I also told him that Governor Hauser was the man for him to see, as the Governor was running a smelter at Wickes on lead ore. I did not assay Jim's ore, nor did I say anything about concentrating, for the ore brought to Toston was solid galena." In further notes, Mr. Austin says that Jim Wardner was original and entertaining. He was generally liked. There is a story that while at Rossland, in later years, he persuaded the Canadian Pacific Railway agent to telegraph to headquarters for a pass to Toronto. The reply read: "Don't let Jim walk." The operator

was something of a joker and handed the telegram to Wardner thus: "Don't. Let Jim walk." 'Jim' was optimism personified; he would tackle anything. Mr. Austin concludes by saying: "He was one of those original characters, products of Western life when doors didn't have locks on them and one was sure of a welcome wherever one went. I don't think Jim was a paragon, but if I had to choose between him and the fanatics that are 'reforming' the world, I'd take Jim." Same here.

Wardner told his story to the Governor, who sent an 'expert' to examine the mine, the result being that Hauser agreed to provide the machinery for a 100-ton concentrator. Wardner's proposal was that he was to secure "a contract to concentrate 50,000 tons at \$5 per ton and also a share in the net profits". Things went well. The mill helped the mine to make money. It attracted the attention of capitalists and was sold to Simon G. Reed, of Portland, for \$650,000.

Of the four locators, Mr. Goetz is now living at Spokane, where he is the proprietor of the Coeur d'Alene hotel, a rendezvous for the people of the mining districts and an attractive hostelry. He seems to have prospered not only in wealth, but in friends and reputation. Kellogg died a pauper 20 years ago. O'Rourke is a broken-down man in a Catholic institution at Vancouver, Washington. Sullivan went to Butte and engaged in mining, using the money he made out of the Bunker Hill; but he did not succeed. In 1901 he joined a party that went to Alaska. While they were engaged in prospecting, two pirates broke into their camp and murdered all except a man named Rooney, who was found under a canoe by some friendly Indians. He was unconscionable and nearly dead, but survived to tell the ghastly story. The party had \$3000 in cash with them and supplies enough to last for a year, all of which were stolen. So the Bunker Hill did no good to its immediate discoverers, for Mr. Goetz, luckily, it would seem, escaped from that category.

The burro fared best of them all. When superannuated he was pensioned off by Kellogg and placed on a farm at Cottage Grove, Oregon, where he died full of years and honors, even his burial being made an occasion for the expression of lofty sentiments in accord with the myth that had been built to his memory. In his book, under the photograph of the donkey, Wardner writes: "The \$4,000,000 donkey in the foreground." Yes, he remained in the foreground a long time, and I am almost sorry to relegate him to the background.

The Bunker Hill story, as twisted and elaborated by the gossip of the campfire, has always centred around the donkey. It seems a pity to spoil a story so well established. Miners are not unlike other men in their faculty for evolving myths, which "represent the protest of romance against the commonplace of life". As Sir Walter Raleigh is better remembered for the tale of the cloak and Queen Elizabeth than for the founding of Virginia, so the legend of the donkey has done more for the fame of Noah Kellogg than the desultory prospecting that ended in the finding of the Bunker Hill lode.

(To be continued)

Experimental Flotation of Low-Grade Quicksilver Ore

By E. G. STOWELL and WILL H. COCHILL

INTRODUCTION. A co-operative agreement between the U. S. Bureau of Mines and the Oregon Bureau of Mines and Geology provides for joint experimental work to encourage the application of improved methods of mineral concentration to the low-grade ores of Oregon, in cases where the problems involved are of such a character as to make the information thus gained useful in solving similar problems in other States. This paper gives the results of one of these investigations. It deals with the experimental flotation and table concentration of a cinnabar ore. The work was done in the laboratories of the Seattle Station of the U. S. Bureau of Mines, and of the College of Mines, University of Washington, Mr. Stowell being detailed from the staff of the Oregon Bureau of Mines, and Mr. Coghill from the U. S. Bureau of Mines.*

The ore from the Black Butte mine, at Black Butte, Oregon, was selected because, first, the nature of the ore was such as to make its treatment a problem of general interest, and, second, the company had made an earnest effort to solve its problem, but had met with indifferent results. The sample was prepared by E. D. Crane, superintendent of the Black Butte mine.

THE MINE, smelter, and mill are at Black Butte, 17 miles south-east of Cottage Grove, Oregon. It is our understanding that there is a large tonnage of ore available carrying 0.15% mercury, and that a long life of the mine would be ensured if an economic extraction could be effected. The soft nature of the ore and the location of the deposit are favorable to low operating costs. Water-power is available during a part of the year, and the company has recently completed an auxiliary steam-plant utilizing the wood fuel abundant in the region.

On the property is a 40-ton Scott furnace, which has operated on a feed assaying between 0.25 and 0.50% mercury. Ore of this grade, however, makes up but a minor portion of the reserves, the remainder being too low-grade to be treated by present methods.

THE MILL. During the past two years the operators have maintained an experimental mill, which, at various stages, has combined gravity and flotation methods. One of the ore-circuits used in this mill is shown in Fig. 1. The essentials of the equipment are: jaw-crusher, Marcy

mill, Dorr classifier, a small rougher and a cleaner flotation machine of the Minerals Separation type, Dorr thickener, and drying vat.

It is reported by Mr. Bray, mill superintendent, that the best recovery by flotation was 80% in a concentrate assaying 4.6%. This grade of concentrate and percent-

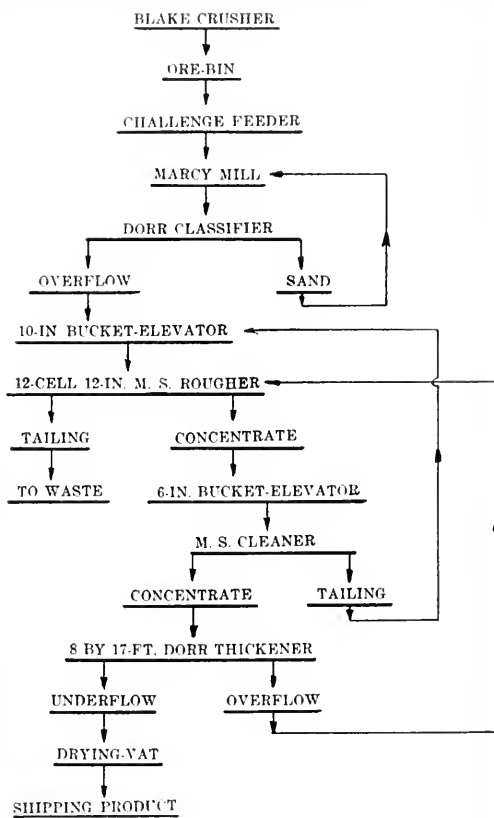

FIG. 1. FLOW-SHEET OF BLACK BUTTE PILOT MILL

age of recovery were not satisfactory; the improvement of these two factors constitutes the problem treated in this paper.

OCCURRENCE AND CHARACTER OF THE ORE. The quicksilver occurs as the sulphides, cinnabar and metacinnabarite, both of which have the chemical formula HgS . The cinnabar is bright red and the metacinnabarite is black.

*The writers wish to thank C. M. Bouton for assaying the ore samples; his work has proved that the method which he has devised for the assay of mercury ores is remarkably accurate for both low-grade and high-grade ores. Acknowledgment of assistance is also due to Milnor Roberts, Dean of the College of Mines, University of Washington, H. M. Parks, Director of the Oregon Bureau of Mines and Geology, F. K. Ovitz and C. O. Anderson of the Bureau of Mines.

The ore-body is in a broken shear-zone in andesite.¹ The higher-grade ore occupies a width averaging 16 ft. across the main fault zone and several hundred feet along the strike. Mineralization, however, has extended through both the so-called foot-wall and hanging wall, but the limits of mining are determined rather by assay than by the appearance of distinct lode-walls.

Flowage and brecciation of the original rock are apparent in hand specimens. The ore is soft and pinkish gray. Cinnabar is seldom discernible without magnification. Pyrite and marcasite may be easily identified, and they amount to about 1% of the mass.

The andesite is altered so that its former character is obscured. Ferro-magnesian silicate minerals have almost entirely disappeared, and in their place some chlorite and limonite in abundance have been produced. Feldspars have altered to kaolin and sericite. No evidence was found that the mineralization took place at different periods, unless the occasional occurrence of marcasite coated with cinnabar may be taken as such.

The mercury sulphide invariably occurs in the softer kaolinized portion of the rock, with other sulphides; sulphides are absent in the less altered portions. Accessory minerals are pyrite, marcasite, stibnite, sphalerite, and

terlocked calcite and sericite. It also contains cinnabar.

Plate B, shows the kaolinized portion, photographed in natural light. It contains pyrite, chalcocopyrite, stibnite (S), calcite, sericite, metacinnabarite, and cinnabar. The unlettered dark grains are cinnabar; the others may be identified by means of the legend.

Many sections were made, and all of them showed that the cinnabar occurs in the softer portions of altered andesite; it is generally wholly imbedded in this softer material, but occasionally it occurs at the contact with the harder fragments.

An important fact to be borne in mind is that the harder material is soft in terms of the hardness of average ores; the results of screen and chemical analysis shown in Table I will then be readily understood.

TABLE I.—Screen* and Chemical Analysis of Black Butte Cinnabar Ore
(Assay of composite sample, 0.145% mercury)

Mesh	Mmms	plus		Proportion of	Assay in
				total weight	
				%	% Hg
20	35		21	0.15
35	65		25	0.15
65	100		8	0.19
100	200		12	0.18
200			34	0.13

*Tyler standard screens were used throughout the work

PLATE A

PLATE B

chalcocopyrite; the last three are present in very small amount. Some quartz, apparently secondary, was observed, also magnetite, which was probably a constituent mineral of the original rock.

The micro-section, Plate A, makes a splendid distinction between what has been referred to as the softer kaolinized portion and the less altered fragments; the dark portion of the field shows the kaolinized portion with specks of cinnabar (retouched with india ink) disseminated through it, and the large, nearly rectangular, portion is a fragment of the original rock. The lath-like pieces of feldspar in this fragment should be noted. The spaces between them are filled with limonite resulting from the alteration of ferro-magnesian silicates. The square light-colored portion at the right consists of in-

The sample for screen-analysis was crushed in rolls to pass 20-mesh and then screened. The chemical analysis shows a remarkably uniform distribution of the mercury on the successive meshes—a slight enrichment in the intermediate products and some impoverishment in the fine. A microscopic examination of the separate products showed that each contained locked cinnabar. The conclusions, therefore, are:

(1) The cinnabar is very finely disseminated. (2) The more altered and softer portions contain the cinnabar, and the brecciated fragments are barren. (3) The cinnabar resists crushing equally as well as the gangue. (4) Fine crushing will be required to release the mineral.

PREPARATION OF SAMPLE. The lot of dry ore weighing about 250 lb. was crushed with a Blake crusher to pass $\frac{1}{2}$ -in. ring and further reduced by rolls to pass 10-mesh. After thorough mixing, a 10-lb. sample was reduced to 40-mesh in a disc-pulverizer. It assayed 0.145% mercury.

It will appear later in the report that though the head assay is 0.145%, assays are shown carrying as much as 0.19%. This variation is explained as follows: The material reserved for testing was stored in a tub that was subject to vibration in the laboratory. The vibration caused the heavy minerals to be concentrated in the lower stratum and thus gave the effect of 'salting'. When this was discovered, the lot was re-mixed and feed-samples of each test were assayed.

TABLE CONCENTRATION was tried before beginning flotation. Three tests were made on a 12 by 24-in. Wilfley table. The results are given in Table II.

The first test was of a preliminary nature to determine

¹Parks, H. M., and Swartley, A. M., 'Mineral Resources of Oregon'; Oregon Bureau of Mines and Geology, Vol. 2, No. 4, p. 33.

the deportment of the material. The recovery was low, 41.3%, and the middling assayed the same as the feed. The tailing was divided into sand and slime. The latter gave the higher assay, but probably not as high as it would if the gangue were of a more resistant material.

In the second test 3000 gm. of the ore was ground in rolls to pass 20-mesh. Five products were made by screen-sizing. These were treated separately, and concentrates, middlings, and tailing were made. The intermediate screen-product showed the best recovery, and the combined products gave a recovery of less than 50%. The middlings were a little richer than the feed.

In the third test a larger quantity of ore was prepared. The results are as in test No. 3 except that flotation of the finest product gave an added recovery of 13.3%. The flotation concentrate was of about the same grade as the average of the table concentrates, but the method of flotation was inferior to that reported below.

Table II—Concentration Tests on a 12 by 24-in. Wilfley Table

Number of test	Weight test Gm.	Mesh	Ratio of concentration	Grade of concentrate % Hg	Recovered %
1	400	—100	31:1	2.07	41.3

		Added recovery by flotation of minus 100 mesh			
	13.3			

Further survey of Table II shows that the coarse gave a low recovery; the loss was probably in the locked grains. Smaller sizes—from 65 to 100 mesh—gave a fair recovery. But the smaller sizes are not at all suitable to table-treatment. Probably a vanner could be substituted. However, the results did not warrant further work by gravity concentration, so flotation was tried.

FLOTATION. It was stated above that the mill-concentrate obtained by flotation assayed 4.6%. Further, it was learned by conference with the operators that their work had been with heavy oils. Since the heavy oils had given such an undesirable grade of concentrate, and since qualitative tests showed their undesirability, it was decided to disregard them in the experimental work and give preference to the light oils.

A series of qualitative tests was made to determine the deportment of a few of the oils in neutral, acid, and alkaline solutions. In general, it was found that the heavier and more insoluble oils produced voluminous persistent froths, floating both cinnabar and pyrite, and entraining such great quantities of gangue that they precluded the cleaning of the concentrate to a desirable grade. On the other hand, a light soluble oil gave a light friable froth well armored with cinnabar and carrying only a small amount of gangue. The concentrate

could be cleaned to make a surprisingly rich product. Caustic soda and sulphuric acid solutions seemed to have no qualities to justify their use. In consequence, light (partly molecularly soluble) steam-distilled pine-oil was selected.

The ball-mill was a more desirable grinding device than either the porcelain jar or the disc-pulverizer. The reason for this preference, and the acidity of the ore, will be discussed later.

In the tests that follow no effort was made to alter the natural chemical condition of the charge after ball-mill grinding, that is, no chemicals were added. However, this does not mean that soluble inorganic compounds were absent.

PROCEDURE. A series of three tests was run to determine the desirable degree of grinding. The flotation charge of 3000 gm. was prepared by grinding minus 10-mesh material in the ball-mill. The pulp-ratio during grinding was 2:1 (water to solid), and during flotation, 4:1. The mechanical type of agitator was used, and the period of roughing treatment was 30 minutes.

Following the roughing operation, the concentrate was transferred to a smaller machine for cleaning. This treatment was continued as long as there were colors in the froth—20 to 40 minutes.

Table III—A Series of Tests to Determine the Desirable Degree of Grinding

No. 1					
Grinding period	Products	Weight Gm	Percentage of total weight	Assay % Hg	Percentage of total mercury
15 min.	Feed	3000.00	100	0.16	100
	Concentrate	6.42	0.214	41.70	59.8
	Middling	17.40	0.58	0.54	1.8
	Tailing	2920.00	97.33	0.07	42.5
	Error or loss	+56.18	+1.88	...	+1.1
No. 2					
30 min.	Feed	3000.00	100	0.16	100
	Concentrate	7.70	0.256	43.00	70.2
	Middling	29.00	0.97	0.54	3.3
	Tailing	2945.00	98.17	0.04	24.5
	Error or loss	+18.30	+0.61	...	+2.0
No. 3					
45 min.	Feed	3000.00	100	0.18	100
	Concentrate	6.94	0.231	55.40	71.1
	Middling	199.00	6.63	0.43	15.9
	Tailing	2755.00	91.83	0.025	12.7
	Error or loss	+39.06	+1.31	...	+0.3

Table III gives the results of these tests. The period of grinding in the ball-mill is the only variable in the procedure. The recovery is 59.8, 70.2, and 71.1% for the respective 15, 30, and 45-minute periods of grinding. The ratio of concentration in the roughing is about 100:1 and the final ratio in the cleaning is about 400:1. The richest concentrate assays 55.4% mercury—a remarkably rich product for a two-treatment system handling such low-grade material. The consumption of oil is 0.7 lb. per ton of ore; it was added at intervals to the impeller compartment of the flotation machine.

The screen-analysis of the respective tailings is shown in Table IV. The increased fineness due to prolonging the period of grinding is here shown by the percentage passing 200-mesh, namely, 52.3, 71.2, and 82.5. The consistent increase of recovery as stated above and the more striking order of extraction values, namely, 61.6, 73.5, and 87, respectively, with increased fineness indicated that fine grinding was desirable.

Since the recovery and extraction showed a continued rise with increased fineness of the ore, it was determined to carry the fine grinding one step further. Therefore, 3000 gm. of the 10-mesh ore was ground wet in the ball-mill for 30 minutes, then screened on 100-mesh and the oversize returned for further grinding. The combined products were then treated nearly as before. The duration of the roughing treatment was only 20 minutes.

Table IV—Screen-Analysis of Tailings from Tests to Determine Desirable Degree of Grinding

Mesh	—No. 1—		—No. 2—		—No. 3—

Minus 300	47.7	...	63.3	...	74.4	...

The rougher overflow was cleaned in the same machine, making concentrate and middling. The duration of the cleaning treatment was 20 minutes, the pulp density was 20:1, and the oil (steam-distilled pine-oil) used amounted to two pounds per ton of original ore.

The results are shown in Table V. There it will be seen that the ratio of concentration in roughing was about 8:1, and that the final ratio of concentration was 220:1. The concentrate assays 35.6% and contains 86.1% of the mercury. The middling is remarkably low-grade—even lower than the feed—and contains only 7.3% of the mercury. If it is assumed that 60% of this middling is recoverable in a concentrate of the same grade as the one shown, a 35.6% concentrate and 90% recovery from an ore assaying only 0.19% mercury is obtainable. A much richer product could be obtained if desirable, as shown by Table III, where one of the concentrates assays 55.4% mercury.

The screen-analysis of the stage-crushed material is shown in Table VI. At first thought it seems that crushing 88% through 200-mesh is excessive, but when the softness of the ore is taken into account, it is probable that the cost would not be prohibitive.

The oil was quick in making a froth and only when used in excess was there difficulty on account of free oil getting into the spitzkasten and killing the froth. A test was made in which a portion of the oil was ground with ore. Apparently no advantage was gained by this procedure, except that frothing started at once with agitation in the roughing-cell.

Comparative tests were made to determine the effect of different pulp-ratios. The ratios used varied from 4:1 to 12:1. In the same interval of time the recovery was greater in the more dilute pulps and the concentrates could be cleaned to better grade. Although the pulp-ratio in the main tests was 4:1, it may develop in practice that the ratio of 6:1 would be more desirable.

A series of tests was made to compare the pneumatic and mechanical agitation types of machines. Fineness of grinding, amount of oil, and other factors were maintained as nearly the same as possible. The results were distinctly in favor of the mechanical type. Extractions

from the pneumatic cell ranged from 37% on the coarsest pulps to 70% on the finest, while the other gave extractions ranging from 60 to 80% on pulps of the same character. The coarser particles of cinnabar showed a tendency to bed down on the canvas bottom of the pneumatic machine and floated with reluctance. This work, however, was not carried far enough to condemn the use of the pneumatic cell.

GRINDING AND ACIDITY. Reference has been made above to the dependence of the results upon the method and degree of grinding; the best results were obtained after fine grinding in the ball-mill. No effort was made to alter the natural chemical condition of the pulp after ball-mill grinding, whereas a similar procedure with a porcelain jar gave adverse results.

The chemical effects of the water-soluble salts of the ore must surely be considered unless we regard flotation as such a mysterious process that it defies the application of chemistry. It would be strange indeed if this ore did not contain water-soluble salts, for, as stated above, the gangue consisted of altered andesite; iron, magnesium, sodium, aluminum, and potassium salts, were therefore formed. If these salts have not been washed away by natural agencies they will appear as water-soluble constituents of the ore.

The water-soluble acidity (by the method of titrating employed in cyaniding) of the ore when washed with two parts of water was equivalent to 0.2 lb. of lime per ton of ore, but this 'acidity' could not be detected with methyl orange as indicator except by boiling down to a concentrated solution. The water-washed ore when treated with lime-water for five minutes gave a latent acidity equivalent to 2.3 lb. lime per ton of ore; the total acidity, therefore, was 2.5 pounds.

The first assumption was that this latent acidity was an adsorption effect and would thus depend upon the amount of solid surface. But tests showed that it was independent of the degree of crushing. It is then a chemical reaction; also it is progressive in its action, so that in a five-minute treatment 2.5 lb. of lime was consumed as compared with 4 lb. in one hour.

The addition of lime to the wash-water gave a precipitate that looked like a ferric salt; exposure to the air caused a reddish turbidity, also suggesting an iron salt. Iron was then identified. Analysis of the wash-water showed the presence of iron, magnesium, calcium, aluminum, and the sulphate radical. Further water-analysis showed that the ore, after wet-grinding in the ball-mill, gave much more soluble iron than when other methods of

washing—including grinding in a porcelain jar—were applied; some of this iron was in a ferrous state, as indicated by a green precipitate with ammonia. Any method of washing where metallic iron was absent showed the presence of ferric iron, but no, or very little, ferrous iron.

The above chemical deportment may now be easily explained: Ferric salts hydrolyze in water, and accordingly give an acid reaction. The acid dissolves iron from the steel parts of the mill. From the standpoint of flotation, the fact that iron (ferrous) is taken into solution is secondary to the fact that the acidity of the solution is thus neutralized, whereas in cyaniding the reverse is true.

The above reaction of ferric sulphate upon iron has been considered once before.² Then a stamp-mill tailing was being cyanided. The cyanide consumption was low until the tailing was re-ground in a disc-pulverizer, and then it was excessive. Investigation proved that the ferric sulphate in the ore reacted with the steel surfaces of the pulverizer, forming ferrous iron, which is a vicious cyanicide.

Aluminum sulphate and potassium aluminum sulphate, respectively, in dilute solutions, react on steel in a manner similar to ferric sulphate, that is, with the production of ferrous iron. This was proved by agitating the solutions respectively in a clean ball-mill and determining the iron in solution.

Let us now go back to the problem in hand; the recovery of cinnabar was much better after neutralizing the acid by grinding in the ball-mill than it was when the acid persisted, as it did after grinding in the porcelain jar. The consideration of the deportment of ferrous sulphate in the flotation machine must not be overlooked. If it instantly oxidizes to ferric sulphate, the aforesaid acid condition will have recurred and the good effects of grinding in the ball-mill will be lost. If it oxidizes slowly, some advantage will be derived. It is likely that this oxidation would progress slowly, if at all, in the presence of the reducing conditions imposed upon it by the organic and inorganic reducing agents present. Unfortunately this cannot be stated accurately because it was difficult to titrate the solution for ferrous iron at the end of the flotation period. The consideration of the chemistry of the process did, however, lead to the solution of a mystery. It served as a guide for outlining the next flotation test, for it suggested neutralizing the acid in some other manner.

A preliminary flotation test was made, therefore, in a dilute lime-water solution and it indicated that the lime had a beneficial effect. Next, a series of tests was arranged to show the relative effects of lime-water, tap-water, and sulphuric acid solutions. The results are shown in Table VII. Note how in passing from left to right—from alkaline through neutral to acid solutions—the mercury extracted amounts to 90.2, 77.6, 61.8, 39.4, and 35.4%.

²Natural basic ferric sulphate is known to occur in two forms, jarosite and uhtahite.

³Coghill, Will H., 'Ferrous and ferric iron in cyaniding'; M. & S. P., Oct. 16, 1915, p. 598.

Table VII—Relative Effects of Lime-Water, Tap-Water, and Sulphuric Acid Solutions on Mercury Extraction by Flotation

Description	Lime-water added Acidity of solution 100 pounds CaO per ton		Tap water Acidity of solution 100 pounds H ₂ SO ₄ per ton	
	Before flotation At 6°C. flotation 0.01	Before flotation At 6°C. flotation 0.40	Before flotation At 6°C. flotation 0.20	Before flotation At 6°C. flotation 0.60
Number of test	1	2	3	4
Per cent mercury extracted	90.2	77.6	61.8	39.4
Grammes pyrite extracted	1.74	0.89	3.22	3.16
Grammes solid in overflow	10.87	10.10	7.99	10.72
				7.53

The ore was ground in a porcelain jar and the inorganic reagents were added at the beginning of the grinding period. The screen-analysis of the tailings showed that the degree of grinding was practically the same as that in test No. 3, Table III, where the ore was ground for 45 minutes in the ball-mill. The extraction, it will be recalled, was 87.0% when the ore was ground for 45 minutes in the ball-mill and no inorganic reagents were used, whereas, the extraction, after grinding in the porcelain jar in the presence of lime-water, is 90.2%. The question now arises: was it the fine grinding that gave the good results shown in test No. 3, Table III, and again in Table V, or was the progressive neutralization of the acid by the steel mill a factor?

Doubtless the advantageous effect of long grinding in the ball-mill was twofold:

(1) The size of the ore particles was progressively and advantageously decreased.

(2) The acidity was progressively neutralized.

Readers who wish to use these notes as a guide to commercial flotation of cinnabar ores will do well to make reference to a paper by C. A. Heberlein on 'Mining and Reduction of Quicksilver Ores at the Oceanic Mine, Cambria, California', in the Transactions of the American Institute of Mining Engineers, Vol. 51 (1915); also Bulletin 78 of the California State Mining Bureau, entitled 'Quicksilver Resources of California'.

MERCURY ASSAY. All assays included in this investigation were made by C. M. Bonton at the Berkeley station of the U. S. Bureau of Mines.⁴ The method was developed at the Berkeley station and has given general satisfaction. The difficulties of assaying these products, in which an error as small as 0.01% seriously affects the interpretation of results, will be appreciated. The method consists essentially of subliming the mercury in a glass tube contained in a heated iron block, then dissolving the quicksilver in nitric acid and titrating with a standard solution of ammonium thiocyanate; ferric salt is used as indicator.

MINING IN TEXAS during 1919 was confined largely to the production of silver. The Presidio mine, at Shafter, Texas, was in continuous operation during the year and small shipments of copper, lead, and zinc ores were made from the Van Horn and Sierra Blanca districts. The production for the State for the year was 540,000 oz. of silver and nominal quantities of gold, lead, copper, and zinc.

A Contribution to the Study of Flotation—III

By H. LIVINGSTONE SULMAN

SURFACE-ENERGY AND SURFACE-TENSION OF SOLIDS

The molecular hypothesis renders the conception of surface-energy equally necessary for solids, whose surfaces must therefore be regarded as being under a tensional strain similar to that existing for liquids.

We are however at a complete loss for any method to quantify or even to estimate the surface-energy of a solid; all such measurements for liquids depend, in one form or another, upon quantifying the force required to extend their surfaces, an operation which is precluded in the case of a solid. In the present state of our knowledge, the order of surface-energy and tension is unknown for solids, though several attempts have been made to estimate its range; that it exists however, and is usually of a high value, is certain. Since the surface-energy of liquids increases with diminishing temperature, it is highly improbable that it will, or can, disappear when the liquid solidifies or freezes; although the heat liberated on solidification (latent heat of fusion) must somewhat diminish the total energy of the solid and will possibly influence the unbalanced forces at its surface. Mercury, having a surface-tension of about 441 dynes/cm. at 0°C., and a temperature coefficient of 0.379 dynes/cm. for one degree C., solidifies at -40. Hence its surface-tension on approaching the freezing-point will be $441 + (0.379 \times 40) = 456.16$ dynes; after making a deduction for the latent heat of fusion it is evident that solid mercury must yet retain high surface-energy.

Widely divergent views exist as to the probable order of solid surface-tensions. By employing a method based upon the heats of solution of large and small particles, Hulett deduced a value of 1100 dynes/cm. for calcium sulphate and 4000 dynes/cm. for barium sulphate. Although these values have been accepted by some physicists, they seem improbably high when regarded from the point of view of flotation experience. The sum of the interfacial tensions of water and barium sulphate would be 4075; but on the addition to the water of 0.02% of sodium silicate (a concentration of 1 in 5000) the barium sulphate is only so far wetted that the contact-angle between solid and liquid is practically reduced to 0°; that is, as will be shown later, the energy of the liquid/solid interface has only fallen to $4000 - 75 = 3925$ ergs per sq. cm.; an altogether inconsiderable reduction of the total assumed energy of the barium sulphate unit surface. Further, on increasing the concentration of sodium silicate to two or three times the former figure, the barium sulphate is entirely deflocculated and put into the condition of a true suspension, which implies its complete wetting, and therefore the reduction of the interfacial energy to zero. If a very small addition of sodium

silicate at first reduces the surface-energy of the solid by merely a few ergs per square centimetre, it appears unlikely that merely doubling or trebling the amount would diminish a remaining interfacial tension of several thousand ergs per square centimetre to zero; from this point of view the estimate of 4000 dynes as the surface-energy of barium sulphate appears excessive, nor does it seem to be in line with that of calcium sulphate, nor comparable with the much lower probable value for solid mercury. Such considerations indicate the unsatisfactory state of our present knowledge of surface-energy for solids.

DYNAMICAL ASPECT OF SURFACES. At the actual surface of a liquid the molecules are in violent motion in all directions. Some are therefore continually projected outward; most are pulled back into the liquid by the attractions of their neighbors in the surface-layer, but those whose velocity is greater than the average (estimated for water at three times the average velocity) will escape into the air; such molecular escapes constitute evaporation. If the liquid be contained in a closed vessel the escaped molecules after numerous collisions with each other and the walls of the vessel tend ultimately to be re-captured at the liquid surface. When the rate of molecular escape is equal to that of return, equilibrium for the liquid at the particular temperature is established. The escaped molecules exercise a definite pressure ('vapor pressure' of the liquid) on the containing walls, and the vapor so produced approximates in constitution to a gas. The surface of a quiescent liquid, though to the eye the smoothest plane, is in reality a seething mass of molecules. Even at a sufficiently lowered temperature where few or none of the molecules finally escape, the surface-layer must still exhibit incessant molecular projections, affording a further reason for the decreased density of the surface-layer. Similar conditions must also obtain at every interface, whether of liquid/liquid or liquid/solid.

Though in a solid the molecular amplitude is smaller, the surface molecules are yet in extremely rapid lateral and vertical oscillation. Very few will escape unless their velocities are sufficiently increased by heat, in which case 'sublimation' results. By reason of such molecular movements the surface of a solid also must be less dense than the interior.

The comparatively loose molecular texture of many surfaces, hitherto unsuspected, has been demonstrated by Beilby,¹ who found that by lightly rubbing copper, calcite, etc., with the finger-tip covered with chamois

¹'The Hard and Soft States in Metals'. G. T. Beilby, Institute of Metals, May 12, 1911.

leather, a surface-layer estimated at 100 μ in depth, and therefore many hundreds of molecules in thickness, will flow under the friction like a fluid. The fluid layer retains its mobility for but a short period and re-solidifies into a vitreous amorphous form, differing from the original surface structure whence it was derived. The new layer is harder than the original crystalline surface and is also more soluble in acids. When completely dissolved away, furrowing effects resulting from the initial friction become visible under a high-power objective upon the exposed and unaltered layer, at a computed depth of probably more than a thousand molecules.

Lord Rayleigh² has also recorded experiments that show a similar flowage in glass surfaces during final light polishing operations. It also appears possible to rub water into glass surfaces by the pressure of the fingers; two surfaces so treated and pressed together will unite

Fig. 2

with such firmness that efforts to detach them by shearing result in the disruption of the substance of the glass on one or other side of the contact.³ The similar effect of wet gelatine allowed to dry upon glass is well known.

Quartz, porcelain, and other hard surfaces are easily stained by rust to considerable depths; if a piece of iron or a ferrous salt be left for some time in contact with porcelain in presence of air and moisture, the resulting stain will penetrate so deeply as to become impossible of removal by hot acids. Roberts-Austen showed that if the accurately faced surfaces of two slabs, one of cast-iron and the other of pure iron, be left together under pressure for a long period carbon will ultimately be found throughout the mass of the originally pure metal.

These and other facts to be noticed later indicate that the surfaces of both sulphide minerals and gangue may undergo profound surface modification during crushing, attrition, water-treatment, etc. Taken in connection with many other facts such as the 'sweating' of oil through iron, of 'cementation', 'case-hardening', 'solid-solution', etc., and with the wide accumulation of knowledge as to the 'sorption' of gases by solids (occlusion, absorption, diffusion, and permeability), the view is strengthened that the surfaces of solids must often be

not only granular but often plastic also, and thus frequently capable of penetration by the molecules of gases, liquids, and even of other solids. Selective-wetting effects obtainable in differential flotation also indicate some degree of surface penetration to be probable. Most solid-liquid interfaces instead of being represented by a mere plane have more probably the constitution suggested in Fig. 2, where the molecules of the liquid are shown as becoming interlocked with or 'rooted' into those of the solid at the plane of contact.

An accumulation of facts shows that most minerals, even when possessing no water of crystallization, have water molecules dispersed throughout their masses; it appears probable that such act as nuclei for the condensation of other like molecules. While they remain, the mineral will be readily wetted by water; but if they are expelled by long heating in vacuum, or by high temperature, the substance is no longer capable of being wetted, for example, fused quartz. The experiments of Tronton (confirmed for quartz, blende, and galena by Edser), of Mellor, Holdcroft, and many others appear capable of no other explanation.

When an apparently dry crystal of galena is freshly crushed, and the powder carefully scattered on the surface of distilled water, a large proportion of the particles sinks. After drying the powder in vacuum over P_2O_5 , or by heat, all the particles float; if, however, galena particles be left submerged in pure distilled water for some time, they partly lose their power of flotation. Freshly crushed quartz particles sink, but when dried in vacuum at high temperature they float perfectly on water, and absorb no moisture from an atmosphere saturated with water-vapor. Fused silica behaves in the same way, water standing upon its surface like drops of mercury upon glass.

Edser says, "the slowness with which this water is given off and its persistent evolution even when the mineral has been heated to 250-300°C. for several hours indicates that the water was originally distributed throughout the substance of the mineral. When once the minerals have been dried in vacuum at high temperature, moisture does not condense on their surfaces from an atmosphere saturated with aqueous vapor." In line with this, Beilby's work and Hardy's experiments with glass indicate that rubbing the solid surface with the liquid will accelerate penetration of the former by the latter.

This view of the granular and porous nature of solid surfaces now offers a rational explanation for the 'hysteresis of contact-angle' between solid and liquid surfaces, to be considered later. Also of the fact that a drop of liquid placed upon a solid surface does not 'slip' over it as a whole when the surface is tilted; the molecules of the fluid appear more or less strongly anchored in the solid, and all movement of the liquid is due to the mobility of its molecules above the plane of contact. This is confirmed by observations as to the 'skin-friction' of a ship which occurs between the film of water carried by the ship's surface and that passed through, and in the phenomena of lubrication, where the oil-film does not slip

²Trans. Optical Society, Vol. xiv, October, 1917.

³W. B. Hardy, Jour. Soc. Chem. Ind., p. 7 T, January 1919.

over the surfaces it lubricates but is sheared at an intermediate layer of its own substance.

INTERFACIAL TENSION. As the degree of adhesion between a solid and liquid determines the interfacial tension at their contact plane, a clear understanding of the term is necessary so far as the recondite nature of the occurrences permits.

Let two dissimilar substances, A and B, be in contact at a common interface, and let the molecules of A attract each other more than they attract those of B; then the molecules in a layer of A at the interface will possess more energy than the molecules in the interior of A. Similarly if the molecules of B attract each other more than they attract those of A, there will be an energized layer of B molecules at the interface. The excess energy of the joint layer at the interface will produce an interfacial tension, which among other effects resists lateral extension. The interfacial tension between two liquids can be measured in various ways; by drop-forming, by the oscillation of drops,⁴ by the method of ripples, but more satisfactorily, where possible, by weighing. Interfacial tension between solid and liquid is therefore due to the energy stored in the solid and liquid on both sides of the contact; within limits it is quantifiable by the angle of contact made between the liquid/air and solid/air surfaces.

If σ_1 be used to represent the surface-tension of the liquid phase and σ_2 that of the solid phase, σ_{12} is the accepted method for expressing the tension of the interface between them when they are in contact.

Then σ_1 = the work done in creating 1 sq. em. of the free liquid surface

σ_2 = the work done in creating 1 sq. em. of the solid surface

σ_{12} = the work done in creating 1 sq. em. of the solid liquid interface.

Also let W_{12} be the work done in separating 1 sq. em. of the interface into two fresh surfaces of 1 sq. em. each, having energies respectively of σ_1 and σ_2 .

Let W_1 be the work done in similarly separating the liquid at a plane of unit area into two fresh liquid surfaces of energy σ_1 .

Let W_2 be the work done similarly per unit area of solid in separating it into two surfaces of energy σ_2 .

Imagine the solid and liquid surfaces to be brought together. If no work is done in again separating them the total energy of the interface (interfacial tension) will be the sum of the energies of the two surfaces:

$$\sigma_{12} = \sigma_1 + \sigma_2 \text{ when } W_{12} = 0$$

This would mean that the molecules of the liquid exert no attraction whatever across the interface upon the molecules of the solid, and vice versa, so that no

⁴If drops of an oil, lighter than water, are allowed to rise through water, they will be observed to oscillate, becoming alternately oblate and prolate spheroids; the higher the interfacial tension the more rapid the oscillation, whence by comparative methods the value may be deduced.

adhesion exists between the substances; the strain in the system is unrelieved and the interface will exhibit maximum tension.

This state is hypothetical, and no instance of complete 'non-wetting' is known; this would involve a contact-angle (written Θ) of 180° , whereas the highest known angular value for a solid liquid contact (mercury/glass) is about 148° , though higher contact-angles occur be-

FIG. 3

tween several immiscible liquids; in every case therefore some degree of wetting, that is, adhesion, occurs.

Next let us consider the *interfacial tension in regard to the equilibrium of a bubble attached to a surface*:

The 'contact-angle' Θ is that made between the air/water and the water/solid interface. A point P will there be held in equilibrium by the algebraic sum of the three tensions: the tension of the solid, σ_2 ; the component of the tension of the liquid, σ_1 , resolved parallel to the surface, $= \sigma_1 \cos \Theta$; and the interfacial tension σ_{12} .

Then $\sigma_2 = \sigma_1 \cos \Theta + \sigma_{12}$, $\therefore \frac{\sigma_2 - \sigma_{12}}{\sigma_1} = \cos \Theta$.

If this condition is complied with the bubble (neglecting gravity as may be done when the bubble is small) will be in equilibrium and will not alter in configuration.

The above is the general expression connecting inter-

FIG. 4

facial tension with the magnitude of the contact-angle, and expresses the fact that, within certain limits considered later, the extent to which the surface tension of any given solid is reduced, by contact with the liquid at the interface between them, will determine the angle of contact between the air liquid and liquid/solid interfaces. The amount by which the original total tensional energies of the two phases is reduced depends upon the degree of adhesion established between them. When no reduction takes place interfacial tension is maximum and adhesion nil; when the reduction is complete adhesion reaches the maximum and interfacial tension becomes zero.

Statistical Review

Production of Metal Mines for 1919*

Montana

The value of the gold, silver, copper, lead, and zinc mined in Montana in 1919, according to the estimate of C. N. Gerry, was more than \$66,307,000, a decrease of about \$55,098,000 from the value for 1918. All the metals but lead showed a decided decrease. On account of the low prices for copper, lead, and zinc, the mines at Butte, soon after the first of the year, reduced their output to about 60% of normal. Production from the mines was not seriously affected by strikes, although there was some labor trouble in February.

GOLD. The value of the gold output fell from \$3,104,764 in 1918 to about \$2,272,000 in 1919, a decrease of nearly 27%. The main decrease was the output of gold derived from copper ores; there were slight decreases of gold derived from iron ore, silicious ore, and from dredging.

SILVER. The mine output of silver decreased from 16,797,479 oz. in 1918 to about 13,281,000 oz. in 1919, and the value of the output decreased from \$16,797,479 to about \$14,768,000. In 1918 and 1919 Montana was the leading silver producer of the United States. In 1919, as in past years, most of this silver came from copper ores, but a large part was obtained from residues from zinc ores, both those smelted in the East and those treated in the electrolytic plant at Great Falls, Montana. The principal producers of silver were the Anaconda Copper Mining Co., Butte & Superior, Elm Orlu, North Butte, East Butte, Davis Daly, Butte Reduction Works tailing dump, and the Granite-Bimetallie mine, at Philipsburg.

COPPER. The output of copper decreased from 323,174,850 lb. in 1918 to about 180,246,000 lb. in 1919. This represents a decrease of 142,928,000 lb. in quantity and \$45,884,000 in value. The average monthly production of the smelting plants of the Anaconda Copper Co., at Great Falls and Anaconda, according to published statements, was nearly 13,000,000 lb. of copper, as against 24,500,000 lb. in 1918. The Pittsmont plant of the East Butte Co. produced more than 1,500,000 lb. per month, instead of 2,000,000 lb., as in 1918. In addition to the mines of the Anaconda and East Butte companies, the North Butte, Davis Daly, Butte Reduction Works dump, Butte Ramsdall, Elm Orlu, Butte Duluth, Butte & Superior, Tuolumne, and Bullwhacker produced considerable copper.

LEAD. The mine production of lead increased from 37,135,875 lb. in 1918 to about 42,163,000 lb. in 1919, but the value of the output decreased from \$2,636,647 to about \$2,411,737. A large part of the lead was obtained from the lead-zinc ores of the Butte district. The Snow

Storm mine, at Troy, Lincoln county, and the Angelica mine, in Jefferson county, were also notable contributors. By-products from the electrolytic zinc plant at Great Falls have added greatly to the totals of both silver and lead. The lead smelter of the American Smelting & Refining Co., at East Helena, was active on ores and concentrates, most of them shipped from Idaho and Montana.

ZINC. The output of recoverable zinc in Montana decreased from 209,258,148 lb. in 1918 to about 176,132,000 lb. in 1919. The value of the output decreased from \$19,042,491 to about \$12,915,000. The principal zinc producers of Montana were the Butte & Superior, Anaconda, Elm Orlu, and Butte Copper & Zinc mines. Smaller producers were the Snow Storm mine, in Lincoln county; the Davis Daly, at Butte; and the Montana Consolidated, in Jefferson county. Most of the zinc concentrates were smelted in the East, but zinc ore from the mines of the Anaconda Copper Mining Co. was concentrated at Anaconda and the concentrates were leached at Great Falls. The electrolytic plant was active during 1919, but the output was less than that of 1918, when much custom material was treated.

The dividends paid by Montana companies for the first eleven months of 1919 amounted to about \$10,590,600. The principal dividend payers were the Anaconda Copper Mining Co. and the Barnes King Mining Company.

Nevada

The value of the gold, silver, copper, lead, and zinc mined in Nevada in 1919 was about \$23,634,000, according to preliminary figures compiled by Victor C. Heikes. This is a decrease of over \$24,894,124, or more than 50%, from the output of 1918, when the mines produced \$48,528,124. The decrease was general, but in point of value the largest decrease was that in copper, which amounted to more than \$19,114,000.

GOLD. The gold output decreased from \$6,619,937 in 1918 to \$4,718,000 in 1919, a decrease of 29%. The Goldfield Consolidated has for several years held the record of being the largest gold producer in Nevada, but in 1919 the company ceased operations and the property was turned over to a developing company. The output of gold from the Tonopah district also decreased notably, amounting to only \$759,000, against \$1,287,745 in 1918. The Elko mine, at Jarbidge, was the largest producer of gold in the State. Other gold mines that had an output of more than \$200,000 each were the Nevada Consolidated, Fairview Round Mountain, Florence Goldfield, and Consolidated Virginia.

SILVER. The mine production of silver decreased in

*From preliminary reports of the U. S. Geological Survey.

quantity from 10,000,599 oz. in 1918 to 7,177,000 oz. in 1919 and in value from \$10,000,599 to \$7,982,000. About 3,535,000 oz. of silver was produced in the Tonopah district, where the principal contributors were the Tonopah Belmont, Tonopah Extension, Tonopah Mining, and West End mines. Large quantities of silver also were produced by the Nevada Wonder, in Churchill county, and the Rochester and Nevada Packard properties, in Pershing county. Smaller outputs were made by the Yellow Pine, Prince Consolidated, Elko Prince, and several properties at Virginia City. The Comstock district produced about 240,000 oz., and several properties at Rochester produced about 575,000 ounces.

COPPER. The mine output of copper decreased in quantity from 116,316,441 lb. in 1918 to 51,000,000 lb. in 1919, and in value from \$28,730,161 to \$9,616,000. The Nevada Consolidated, at Ely, in White Pine county, was the largest producer and contributed more than 3,500,000 lb. of copper per month; and the Consolidated Coppermines, in the same county, made a notable though greatly reduced production. The Mason Valley smelter, at Thompson, in Lyon county, was operated for only two months, and the shut-down there resulted in a decrease of more than 1,000,000 lb. of copper per month.

LEAD. The mine output of lead decreased in quantity from 23,316,534 lb. in 1918 to 12,558,000 lb. in 1919, and in value from \$1,655,474 to \$718,000. The Prince Consolidated mine, at Pioche, remained the largest lead producer of the State, and the Virginia Louise, Combined Metals, and Black Metals mines, in the same district, shipped considerable ore containing lead. In Clark county the Yellow Pine mine made a lead production second only to that of the Prince Consolidated, and the Goodsprings Anchor Mining Co. shipped a rich lead concentrate. At Eureka the Eureka Croesus and Eureka Holly companies shipped much lead ore.

ZINC. The mine output of recoverable zinc decreased in quantity from 16,724,753 lb. in 1918 to 8,182,000 lb. in 1919, and in value from \$1,521,953 to \$598,973. A large part of the output came from the Yellowpine district, in Clark county, though there was a distinct decrease from this region. The Consolidated Coppermines, in White Pine county, made large shipments of zinc ore, resulting in a production considerably greater than that of 1918.

Incomplete dividends, declared by Nevada mining companies for the first eleven months of 1919 amounted to \$3,327,188. The principal contributors were the Nevada Consolidated, Tonopah Extension, Tonopah Belmont, Tonopah Mining, West End, Nevada Wonder, Nevada Packard, and Fairview Round Mountain companies.

New Mexico

The output of the mines of New Mexico for 11 months of 1919 and the estimated output for December, as reported by Charles W. Henderson, amounted to \$568,000 in gold, 709,000 oz. of silver, 2,800,000 lb. of lead, 52,200,000 lb. of copper, and 8,000,000 lb. of zinc, as compared with \$682,791 in gold, 782,421 oz. of silver, 8,398,

239 lb. of lead, 98,264,563 lb. of copper, and 24,050,324 lb. of zinc in 1918. These preliminary figures show decreases of \$115,000 in gold, 73,000 oz. of silver, 5,600,000 lb. of lead, 46,000,000 lb. of copper, and 16,000,000 lb. of zinc. All the mines except silver mines suffered from low prices of metal, and increased prices of labor and materials.

The decrease in the output of all metals except gold and silver is startling. Mills of the Mogollon district, Socorro county, produced \$129,000 in gold and 310,000 oz. of silver as compared with \$119,710 in gold and 302,902 oz. of silver in 1918. In 1919 the Mogollon Mines Co.'s mill was operated steadily, but the Socorro Mining & Milling Co.'s mill was closed April 1, and operations were not resumed during the year. The output of gold from the Aztec mine, at Baldy, Colfax county, was not so large in 1919 as in 1918. The shipments of gold-bearing siliceous copper ores from Lordsburg increased heavily, but there was a decrease in the shipments of gold-bearing iron-copper ores from Orogrande.

COPPER. Copper has long been an important metal product of New Mexico, and since operations were begun by the Chino Copper Co. at Santa Rita at the beginning of 1910, the State's output of this metal has been large. The large decrease in the output of copper in 1919 is therefore particularly impressive, for the total output is only a little more than half that in 1918. In 1919 the Chino Copper Co.'s output was 43,992,000 lb., as compared with 79,340,372 lb. in 1918. Beginning in January 1919 with an output less than the average monthly output in 1918, this company curtailed operations to about 50% of its capacity during the rest of the year. The Burro Mountain Branch of the Phelps Dodge Co., which in 1918 produced 53,146 tons of concentrate averaging 14.9% copper, was even more seriously affected by the drop in the price of copper and suspended milling operations early in the year and did not resume. The copper-matting plant at San Pedro was not in operation in 1919 and was dismantled. The 85 Mining Co., at Lordsburg, made a large increase in shipments in 1919, but shipped crude ore entirely that year, as compared with concentrate and crude ore in 1918. The copper ore shipments from Orogrande decreased heavily.

LEAD. The shipments of lead ore from New Mexico decreased heavily. Hardly any lead ore was shipped from the Organ Mountains district, and the shipments from the Central district, Grant county, and the Magdalena district, Socorro county, were less than in 1918, as were also the shipments from the less productive Cooks Peak and Victorio district, Luna county.

ZINC. The output of zinc sulphide and zinc-carbonate ores likewise decreased seriously. The Ozark mill, at Kelly, was operated only in an experimental way, and the Cleveland mill, at Pinos Altos, was operated for only a short time. The Hanover mill was not operated to its full capacity. Much less carbonate zinc ores were shipped from Hanover, Kelly, and Cooks Peak than in 1918. The Republic Co., at Hanover, shipped a considerable quantity of high-grade zinc sulphide ores.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ALASKA

DOCK PROPOSED FOR HYDER.

HYDER.—The little but bustling mining town of Hyder, situated near the Canadian border on the upper reaches of Portland canal, which has the distinction of being the gateway to the newly discovered and promising mining section of the Salmon river, is to have new docks and other facilities for the handling of freight and general

ARIZONA

BONUS-MONEY FOR PHELPS DODGE EMPLOYEES.—BISBEE NOTES.

Douglas.—Approximately \$80,000 in bonus-money was distributed among employees of the Phelps Dodge Corporation and Calumet & Arizona smelting plant on the first pay day in January. At the Copper Queen branch-smelter 440 men received approximately \$52,000. During

HYDRAULICKING IN LOVETT GULCH, YUKON TERRITORY

business, according to a report from Juneau. John Sutherland, a business man of Hyder, it is announced, has filed at Juneau articles of incorporation of the Hyder Dock Co., organized to construct a \$30,000 pier. At present most of the freight billed for Hyder is handled on barges over the tide flats. The new pier will be ready for use, it is hoped, before the commencement of the rush which is expected to begin just as soon as the weather opens in the spring. Inquiry from all parts of the United States indicates that there may be a repetition on a smaller scale of the historic stampede to the Klondike in 1898. The most important mine in the Salmon River district is the Premier (or Bush) mine, developed by R. K. Neill of Spokane. At the present time ore from the Premier is being shipped through Hyder to Seattle.

1919 this smelter paid out approximately \$90,000 to a total of 760 employees. The Calumet & Arizona smelter's January bonus-payment was \$28,620 to 250 men. This smelter paid out approximately \$16,000 additional during 1919 to 150 other men. These sums were, of course, in addition to regular wages, and are in recognition of faithful continuous service. The first year's bonus for employees is \$100 and each succeeding year of service brings an increase of \$10 until the maximum payment reaches \$250. It is claimed that no smelter of similar size in the world has a greater number of men who have been continuously employed. The bonus system was adopted as a profit-sharing measure and to increase the force of permanent satisfied employees by giving a definite reward for continuity of service. That the men appreciate it

is shown by the larger number who share in its benefits each year.

A luncheon was given in honor of A. T. Thomson, assistant to the president of the Phelps Dodge Corporation, who left here during the first week in January for New York. This was made the occasion of presenting Mr. Thomson with a handsome watch and chain as a token of the esteem in which he is held by his associates.

Flags were flown at half-mast for three days on all buildings of the Phelps Dodge Corporation out of respect for James McClean, vice-president of the concern, who died on the morning of January 7. Mr. McClean first associated himself with D. Willis James and William Dodge in importing tin before the company became engaged in mining. When the old firm of Phelps, Dodge & Co. became the Phelps Dodge Corporation in 1912 he became vice-president. His property interests brought him frequently to the South-West and he was well liked and highly respected by those in this section who knew him personally.

HUMBOLDT.—The Consolidated Arizona Smelting Co. reports having produced during December from the Blue Bell and De Soto mines 13,100 tons of ore which was shipped to the reduction plant. The concentrator handled 9200 tons of material while the smelter treated 7400 tons of new ores and concentrates. Shipments of fine copper bullion to the Eastern refinery amounted to 615,000 lb., of which 500,000 lb. was derived from company ores.

BISBEE.—The Boras lease, adjoining the White Tail Deer and the Night Hawk, near Don Luis, was reported on January 11 still to be in oxide ore averaging from 7 to 8%, in the drift it has been running from the 90-ft. winze sunk from the 400-ft. level. The drift after being advanced 34 ft. was still in ore. The main shaft of the Boras is 400 ft. deep. A drift on this level encountered a fault at the point where the winze was started. Shipments to the smelter at Douglas are being made as rapidly as the equipment of the property will allow. A new hoist of larger capacity has been ordered and should arrive from Denver before the end of the month. The Lowell Gold Mining Co., composed of a group of Warren operators, has leased its property in the Quijotoa mountains in Pima county, 80 miles from Tucson. The lease covers a period of five years with option to buy at the end of that time. Considerable development work is planned. A stamp mill will be installed. The owning company is composed of J. L. Winters, president; Fred Henderson, vice-president; John P. Williamson and M. E. Kawn, directors.

HILL TOP. The Hill Top Metals Mining Co. is working a force of 40 men at its silver-lead mine. Driving of the lower tunnel has given way temporarily to cross-cutting, and in the upper tunnels drifts are following the ore in several places, according to R. O. Fife, managing director. J. O. Fife, president of the company, arrived from his headquarters in Kansas City, January 15, to inspect recent work. C. O. Botsford and W. G. Fife, who control the Manhattan, a copper property,

situated near Hill Top, recently inspected it and it is anticipated that they will install machinery soon and re-open the property.

MIAMI.—F. W. MacLennan, general manager for the Miami Commercial Co., has rendered a report to all employees of the Miami Copper Co., Miami Commercial Co., and Miami-Inspiration hospital that as a result of operating the store of the Commercial company on a co-operative basis during November and December a net profit of \$7492 was realized to be distributed in the form of rebates to the employees of the companies named. This amounts to a rebate of 13.9%.

TOMBSTONE.—A new profitable venture, the working of old mine dumps for the silver and lead content, discarded in the 'boom' days of the district, has been started and before long it is believed that several operations of this character will be under way. Al Godfrey and Bert Holland were the pioneers in the field, having recently completed a small concentrator near the Emerald mine, purposing to treat the large dump. The first runs gave excellent recovery and a good profit for the lessees. The concentrator has been built at the foot of the dump and an automatic feed provided to carry the screenings onto the table. This does away with handling from the time it enters the ear to be dumped on the screens until the concentrate is sacked for shipment. A gasoline engine runs the whole plant. There are thousands of tons of workable material on the dump which will require a considerable period to treat. Several other dumps in the district await similar handling. There are approximately 100 leases being operated in the district at present and from 75 to 80 carloads of ore are shipped monthly.

COLORADO

CRIPPLE CREEK DIVIDENDS.—LESSEES ACTIVE AT LEADVILLE.

CRIPPLE CREEK.—Dividends for January to be paid by mining and milling companies in Cripple Creek total \$160,000 as follows: Portland Gold Mining Co. 2c., \$60,000; Golden Cycle Mining & Reduction Co. 3c., \$45,000; United Gold Mines Co. 1c., \$40,000; Vindicator Consolidated Gold Mining Co. 1c., \$15,000. The rich sulphide ore opened up at the twenty-third level of the Portland No. 2 shaft, is said by the mine officials to be the richest discovery made in years at this Battle Mountain property. Precautions have been taken to prevent high-grading, as quartz from the core of the vein, containing crystals of calaverite, is worth many dollars per pound. Miners are required to use the change room and change even their shoes before leaving the property for their homes.

Ore assaying about 1½ oz. gold and 12 to 15 oz. silver per ton has been opened up on the 1200-ft. level of the Blue Flag by the War Eagle Consolidated company. The Blue Flag company is driving to connect with the Moffat or Ophelia tunnel, and thence through the War Eagle property to a point under the Scott or main shaft. Work in the Blue Flag lateral is done under air-pressure on account of the presence of mine-gases, and except for the

ore taken out in drifting no attention will be paid to mining until the connections are completed. Tulley Scott, judge of the Colorado Supreme Court, is president of the War Eagle company. Operations have been suspended in the Gold Coin workings of the Granite Gold Mining Co. in Victor, and the company and some 15 sets of lessees are operating through the Dillon shaft on Battle mountain. Production for January will approximate 1000 tons of ore, ranging in value from \$10 to \$60 per ton. The Granite company is also operating the Bonanza fraction of the United Gold Mines Co. through the Dillon, and is shipping about 100 tons per month of ore containing from two to three ounces of gold.

Daily shipments of good ore are leaving the Modoc Consolidated company's No. 2 or Last Dollar shaft on Bull hill at the rate of 50 tons daily. The Cresson continues

ily and shipments are going to the smelter at the rate of 15 tons per day. The same people are also operating the Griffin property in the St. Kevin district where silver ore assaying between 30 and 50 oz. is being shipped.

The Northern mine at the head of Ninth street is to resume operations. The mine, when closed down about three months ago, was producing a rich silver-chloride ore. Lessees on the Dinero in the Sugar Loaf locality are mining high-grade silver ore and shipping a fair tonnage of smelting ore. Operations have been resumed on the old Matchless mine by A. B. Bailey, representing an Eastern syndicate. It is planned to sink the shaft and carry on deep development. Two sets of lessees at the Dunkin No. 3 and 4 shafts are shipping iron ore to the smelter at the rate of several hundred tons per month.

Consolidations of mining properties situated in the

THE CRESSON MINE, CRIPPLE CREEK, COLORADO

heavy production and with the grade holding up the treasury reserve is again gaining. No dividend was declared for January, but a payment is expected before the first quarter of 1920 closes.

LEADVILLE.—The metal output of the Leadville district for the past year totaled \$6,543,077, with zinc, the chief product, amounting to \$2,466,931. Silver produced was valued at \$2,042,226; lead, \$812,005; gold, \$719,999; copper, \$249,416; manganese, \$245,000; and bismuth, \$7500.

The Fanny Rawlins Gold Mining Co., owning the Fanny Rawlins mine on Breece hill, operated under lease, has resumed payment of dividends with the distribution on February 16 of \$5000. The dividend of $\frac{1}{4}$ ¢ per share is made payable to stockholders of record on January 31. J. A. Himebaugh, president, in his report showed \$13,397 on hand in addition to ore in transit or at the smelter. Recent shipments totaling 391 tons have averaged better than \$40 per ton. The last previous dividend was paid in December 1908. The Long and Derry mine in Iowa gulch, under lease to H. Schraeder, is producing stead-

Graham Park section west of the Iron fault and extending to the Iron-Silver properties are said to be pending. Experimental work is in progress at the plant of the Colorado Concentrating Co., with a new process for concentrating the sulphide ores of low grade. If the experiments are successful a magnetic-separating plant will be constructed.

MICHIGAN

PLANS AT SENECA.—DECEMBER PRODUCTION.

Houghton.—Seneca has completed the south drift on the second level while the north drift has 115 ft. to go before reaching the limits. The third-level laterals will be under way this week. The third-level drift on the vein will run 250 ft. to reach the south limits of the property, but the north drift will run without regard to property limitations. From a mining standpoint the next important thing is to sink the Gratiot shaft to greater depth and then connect up with a lower level of the Seneca. This will have to be done sooner or later to provide the

Seneca with proper ventilation to make mining conditions efficient. The Seneca has to have a permanent hoisting and compressor-plant and ore-house before it can produce on a large scale. The present hoist, which was in use in this district 35 years ago, is doing efficient service but it was designed to use for hoisting-operations down to the sixth level only.

The Seneca stockpile contains 7000 tons of good Kearsarge amygdaloid ore which is being shipped in train-loads of 700 tons. This is enough ore to keep one section at the Baltic mill operating two shifts. The ore-bins and chutes at the shaft have been arranged to dump the ore that is hoisted directly into railway cars.

The Champion mine of the Copper Range company, owned jointly by the St. Mary's Mineral Land Co. and the Copper Range, has the best record of any of the copper mines of the Lake Superior district for the month of December. The production of refined copper totals 1,840,000 lb. This compares with 1,480,000 lb. in November and 1,640,000 lb. in October. The mine continues to maintain its standing as the highest-grade producer, the ore averaging 40 lb. of copper per ton for the month of December. The production of the Champion mine for the year 1919, when officially given out, will show a higher total than generally believed on account of the high copper content which will average 42 lb. for the year. The Baltic mine produced 14,000 tons of ore in December, a decrease of 3400 tons from the month before. The refined output of the mine for December will therefore show 490,000 lb. compared with 626,400 lb. in November, and 697,000 lb. in October.

MONTANA

ANACONDA COMPANY STARTS PRODUCTION AT ADDITIONAL MINES.

BUTTE.—The Butte & Superior, acting for Hayden, Stone & Co., is pushing the development work in the south section of the Butte district. The Mary Louise shaft is being repaired and equipped with machinery preparatory to an extensive exploration. This shaft is south-east of the Emma mine of the Butte Copper & Zinc, which is being prospected by the Anaconda Copper company. The latter will develop some of the veins that pass through the Emma into the Mary Louise claim. A body of ore has been struck on the east side of the Emma property which assays 8 oz. in silver, 15% zinc, and 7% lead. It is stated that the orebody is 12 ft. wide on the 1200-ft. level, but has not been opened to any extent as yet. The Emma is south and west of the Davis-Daly company's Colorado shaft and north-west of the ground being opened by the Hayden-Stone interests.

The Anaconda Copper Co. is now hiring all available experienced men at the Belmont, High Ore, Mt. View, Moonlight, and Poulin mines preparatory to the resumption of active mining in these properties. At least two thousand men will be required when working at full capacity. This will mean that the Anaconda company's operations will be at approximately 80% of normal.

The Butte & Superior produced in December 14,000,000 lb. of zinc and 215,000 oz. of silver as compared with 11,500,000 lb. of zinc and 200,000 oz. of silver in November. The East Butte Copper Co. in December produced 1,815,540 lb. of copper and 71,421 oz. of silver as compared with 1,902,580 lb. of copper and 56,834 oz. of silver during the previous month, a decrease of 57,040 lb. of copper and an increase of 14,587 oz. of silver. The North Butte has been compelled to lay off two of the three shifts at its BIRTHA mine because the leaching plant at Anaconda can handle the output of one shift only for the present.

The Argyle Silver Mining Co. will be operating in the Vipond district in Beaverhead county soon, as J. Benton Leggat has arrived at Butte from Salt Lake, and will at once prepare to open the property, which has not been worked since the early 'eighties. These claims are situated twelve miles south-west of Divide on the Oregon Short Line railroad.

General conditions are picking up in Butte, but are far from normal. This is the hardest winter ever experienced in Butte, because of the curtailed operation of the mines, which, with the severe weather and the coal strike, left at least 3000 families practically destitute; but indications are good for a prosperous year in 1920.

NEVADA

INGALLS PROPERTY IN TULE CANYON FINANCED.—ARROW-HEAD DEVELOPMENT.

TULE CANYON.—The Ingalls mine and the adjoining Jaegers group of six claims have been optioned to Eastern capitalists for \$145,000, the first payment of \$13,000 to be made on February 12, with the others extending over a period of two years. The price for the Ingalls is \$125,000 and \$20,000 for the Jaegers. The Ingalls has been worked for over 30 years and has a production record conservatively estimated at \$200,000. Lessees have produced \$30,000 gross during the past three years and the output from April 1 to October 1 of last year was \$15,000 gross. The average content of several lots was from 10 to 15% lead, \$5 in gold, and 30 oz. in silver. The Jaegers claims are on the strike of the Ingalls vein. The option stipulates that 100 shifts per month shall be worked in the Ingalls and 60 in the Jaegers. In 1914 the Ingalls was open for location, but Sheriff Ingalls of Esmeralda county did not consider it worth while to do the assessment work because of the low price of silver. W. B. Mereer of Goldfield re-located the claims for Ingalls and in this way received a half interest. The work proposed by the holders of the option will be the first on a large scale ever done in the district.

DIVIDE.—One foot of ore assaying \$57 has been opened in the west drift on the 200-ft. level of the Victory. This is the best width of good-grade ore that has been found in the Victory, which is east of the Belcher and on the same vein-system. The west drift is 214 ft. long. A report submitted by A. I. D'Arcy, general manager, at the annual stockholders' meeting, held in Goldfield on January

13, shows that 742 ft. of lateral work has been done on the 200-ft. level of the 220-ft. shaft. All lateral work has been done at this depth. The west drift is being driven in the main vein of the district and a drift also has been extended a short distance east in this vein. The company has \$45,097 cash in bank. A station is being cut at the bottom of the 100-ft. shaft of the Pay and cross-cuts are to be driven north and south to cut veins entering the Pay from the Belcher Ex. and Revert. Sinking of a shaft has been started by lessees on the Beats All claim at a point where rich silver-gold ore was found. Control of the Butte, south of the Belcher, has passed to New York and Boston interests and work is to be resumed through the 150-ft. shaft. No work has been done for several months in a number of prospects in the district.

WEST DIVIDE.—Zeb Kendall, known for his connection

ARROWHEAD. A raise from the 175-ft. level of the Arrowhead has broken through to the 100-ft. level after continuing in ore from a point 15 ft. above the lower level. The south-east drift on the 100-ft. level has been connected with the raise. Assays taken in the raise give average returns of from \$65 to \$70.

UTAH

BINGHAM PRODUCTION.—DIVIDENDS DECLARED BY EUREKA COMPANIES.

BINGHAM.—During 1919 the mines in this district produced a total of 5,913,000 tons of ore, as compared with 13,607,650 tons in 1918. The metal output for the period is estimated at 56,000 oz. of gold, 1,600,000 oz. of silver, 117,000,000 lb. of copper, 54,000,000 lb. of lead, and

ARROWHEAD MINE, NYE COUNTY, NEVADA. MALPAIS MOUNTAIN IN LEFT BACKGROUND

with Divide companies and other mining enterprises in Nevada, is reported to have taken over a large block of stock in the West Divide. This will furnish funds for the purchase of machinery and for development work on a larger scale than heretofore. Julius Goldsmith, president of the Dividend in the Divide district, has become interested in the Silverado, east of the West Divide and on a different vein-system, and it is reported that work is to be started by this company.

GOLDFIELD.—The south-east cross-cut on the seventh level of the Florence is 450 ft. long and the west cross-cut is 650 ft. long. Recent progress to the south-east has been slow because of the necessity for timbering. The west cross-cut is nearing the Columbia Mountain fault and a change in formation is expected soon. The Red Hill has levied assessment No. 5 at the rate of 1½¢. per share, payable immediately. The delinquent date is February 10. Little work has been done in the Cracker Jack recently because of trouble with the compressor.

PIONEER.—Assessment No. 4 at the rate of 1¢. per share has been levied by the Consolidated Mayflower Mines Co. The assessment is payable immediately and the delinquent date is February 1. The report states that the mill has been unable to operate at capacity because of a water shortage. The spring now in use is to be further developed, according to the report.

2,674,00 lb. of recoverable zinc. The heavy decrease in shipments was due to the drastic curtailment in operations at the Utah Copper mine, which was in force throughout the year; the production from this property averaging 9,000,000 lb. of copper per month, as compared with an average of 16,500,000 lb. per month for 1918. The Ohio Copper Co. suspended operations at its mine and mill about April 1, and did not resume during the year.

PARK CITY.—Remarkably rich silver-chloride ore was recently found on the Union Tunnel level of the old portion of the Ontario mine, according to Richard Pelton, superintendent. This vein, which was cut at a depth of 500 ft. below the surface, is from 12 to 18 in. wide. According to Mr. Pelton, the ore assayed from 200 to 400 oz. silver per ton. Recently a shipment of 75 tons was sent to a Salt Lake valley smelter, which averages about 40% lead and 300 oz. silver per ton. This ore is of higher grade than any shipment made from Park City in years. An attempt to recover the rich and extensive ore-shoots, which were found in the Ontario vein, will be made on the east side, where the veins were lost because of the great Ontario fault. All searches on the other side of this fault hitherto have been unsuccessful.

Preliminary operations have succeeded so satisfactorily at the Keystone mine that breaking of ore in three or

four known faces should be started about February 1. By an agreement with the Judge M. & S. company, the Keystone has acquired the right to open up its property through the Anchor tunnel, which had been extended to within 168 ft. of the south side-line of the Keystone at the time work was stopped. It is probable that this entrance into the Keystone property, which gives a depth of 1600 ft., will be used later, when the various veins have been developed and their trend determined by exploration work from the Hanauer tunnel-level above.

Shipments of ore for the week ending January 10 totaled 2292 tons, of which Ontario shipped 850; Silver King Coalition, 549; Judge M. & S., 575; Daly West, 213; and Daly Mining, 105. During 1919, the mines produced a total of 81,457 tons of ore, of which amount Silver King leads with 22,692 tons; followed by Judge M. & S. company with 22,215 tons; Ontario Silver, 21,329 tons; Daly West, 5723 tons; Daly Mining, 3474 tons; Naildriver, 2579 tons; and Silver King Consolidated, 1260 tons. Shipments during December were the heaviest of the year, while the second largest month was January. During June the Naildriver was the only shipper, all other properties being closed down completely, owing to a strike of miners. From the best information available, the value of the gold production in 1919 was \$64,083; while the output of silver totaled 1,800,000 oz.; copper, 625,000 lb.; lead, 20,000,000 lb., and recoverable zinc, 1,350,000 pounds.

James B. Allen, manager of the Glenallen property, reports that within the next thirty days the machinery for the mill will be on the ground, and early summer will see both the mine and mill in full operation.

EUREKA.—The Iron King officials have decided to sink another shaft in the south-western part of the company's large tract in the eastern part of the district for the purpose of developing a promising section of ground which is 2500 ft. from the present workings. The management decided to sink this second shaft rather than drive a long drift, as the gas and heat would be a serious handicap.

Shipments from this district for the week ending January 10 totaled 147 cars, being a slight increase over the previous week's shipments. Mines and carloads as follows: Chief Consolidated, 42; Tintie Standard, 33; Dragon, 11; Iron Blossom, 11; Eagle & Blue Bell, 8; Centennial-Eureka, 8; Gemini, 7; Colorado, 6; Swansea, 4; Mammoth, 3; Grand Central, 3; Sioux Con., 2; Sunbeam, 2; Empire, 2; Ridge & Valley, 2; Bullion Beck, 1; Victoria, 1; Martha Washington, 1.

During the past week, the drift from the new shaft of the Yankee Consolidated cut into very promising quartz, which shows silver and gold on the 1500-ft. level. All of the ore which the mine has shipped has been taken from upper workings, and naturally a great deal of importance is attached to this new work at depth.

D. D. Muir, Jr., mine manager for the United States Mining Co., recently announced that the company would permit leasing on all levels down to the 700, and that the highest royalty the company would charge would be 50%. From this figure it will run down to as low as 15%, de-

pending on the grade of the ore. Most of the local mines that give leases require a higher royalty on high-grade ore. After being without an iron-ore contract for some time, arrangements have been made whereby the Dragon Consolidated company will ship about 60 tons of iron per day to the United States smelter at Midvale, to be used for fluxing purposes. The Dragon has many thousand tons of this ore blocked out, and the contract will add something to the earnings of the property. Directors have declared a dividend of 1c. per share, totaling \$18,750, payable January 26.

Arrangements have been made whereby two headings on the 2200-ft. level of the Iron Blossom mine will be turned over to Walter Fitch, Jr., local contractor, who will take the work up immediately. One of the Iron Blossom drifts is being driven toward the east and the other is cutting a promising section of ground to the north of the shaft. Directors of the Iron Blossom company met at Provo on January 10 and declared a dividend of 2½c. per share, totaling \$25,000.

MILFORD.—Stockholders of the Leonora Mining & Milling Co., at a recent meeting, elected the following board of directors: John Matson, C. D. Brown, J. W. Chase, L. H. Stolars, and B. H. Goddard. At the same time the capitalization of the company was increased by 300,000 shares, all of which was deposited in the treasury.

WISCONSIN

EXPANSION OF OPERATIONS.—NEW MILLING PLANTS UNDER CONSTRUCTION.

HIGHLAND.—The Mineral Point Zinc Co., operating several mines producing carbonate-zinc ore, is reverting to old-fashioned methods of milling by building several log-washers for cleaning mine-run ore. A battery of log-washers it is claimed will recover as much marketable product as a modern concentrator and much more economically.

LUNDEN.—Two new zinc-ore shippers are the Mackay Mining Co., which has taken over the Ross property, and the Fearless Mining Co., which has opened up the ground formerly mined by the Optimo company and has started a new 100-ton mill from which it is shipping concentrate assaying more than 50% zinc.

LIVINGSTON.—The New Jersey Zinc Co. has developed a new mine on the Cushman-Rewey land known as the Coker No. 2, where a mining plant is being built. The Vinegar Hill Zinc Co. has increased its output of zinc ore considerably by the addition of a new 200-ton mill on the Dale mine, operating in conjunction with a larger mill on the Yewdall land. Three distinct veins run parallel to each other, converging at a point west of the Dale mill. West of the Yewdall another mine is being opened up, giving the Vinegar Hill company territory nearly one mile in length. Other producers in the camp that are making ready to resume mining and milling after a shut-down of nearly a year are the Grunow, Lucky-Six, Peacock, New Phoenix, Biddick, Squirrel, and Big Tom mines. Shovelers are in great demand at all points in the district and earn from \$6 to \$8 per shift.

PLATTEVILLE.—The Block-House Mining Co. is engaged in constructing a new 150-ton mill east of the mine, on the Goke property. The ground has been proved with drills, eastward, giving new mining territory over two sections of land. Engineers are now engaged in proving lands east of Cuba City, 14 miles south-east of Platteville, and have taken over the Rowe property, in Shullsburg, where new mining and milling machinery is planned. The Wisconsin Zinc Co. is engaged with drills on a big stretch of land north of the city of Platteville. The site was known in former years for surface-lead and it is believed big deposits will be opened by the Wisconsin company. Nearly all of the large operating concerns represented in the field are extensively engaged in campaigns of expansion. Scores of drills are at work and rich discoveries are frequent. The impression prevails that the next three years will mark extremely prosperous conditions in the industrial life of the country and that a big demand for metals will result.

BRITISH COLUMBIA

REPORTS OF PORTLAND CANAL REGION.—CANADIAN COINAGE LAW CHANGED.

Six of the most capable members of the Geological Survey Branch of the Department of Mines are to leave the service to accept employment with the British oil firm of S. Pearson & Son, Limited, whose headquarters are in London but who operate oil properties all over the world. Those who are going are L. D. Burling, A. O. Haynes, J. J. O'Neill, W. J. Wright, B. R. McKay, and Bruce Rose, most of whom are known for their geological work in British Columbia.

ALICE ARM.—A new townsite at Alice Arm is being planned to replace that now in use which is situated on a mudflat. The survey of the new site now is under way. It is on the side-hill north-west of the present townsite and belongs to the Alice Arm Development Co. Sufficient water is said to be convenient and the installation of other public utilities will not be difficult. In view of the mining development now in progress the enterprise seems warranted.

STEWART.—Grant Mahood accompanied the first winter shipment of 300 tons of ore from the Premier mine to Victoria. Hauling to the coast by tractor was tried, but had to be abandoned and horse transport substituted. Mr. Mahood reports favorable development at the '49 mine, where ten or twelve men are working with satisfactory results. He states that considerable interest is being taken in work in progress on the Lakeview mine, situated on the Bear River side of the Portland canal. This property was taken over last fall under bond by P. Welch and associates.

S. G. Benson, owner of the White Mouse group of mineral claims, situated about two miles beyond the '49, has placed the property in the hands of a syndicate which will start active development as soon as it is possible to haul supplies over the snow crust. Richard Elliott is at the head of the syndicate. He has had considerable mining experience, having been heavily interested in Bear

River properties at the time of the excitement about nine years ago. Mr. Benson states that the White Mouse has promising surface showings. The Sunset group is another Salmon River property on which development will commence as soon as conditions permit. A Vancouver syndicate is furnishing the necessary finances. The Salmon River Mother Lode Mining Co., Ltd., has been incorporated with an authorized capital of \$100,000 and with its head office at Vancouver.

GRAND FORKS.—A contract has been awarded for the driving of about 1000 ft. of tunneling on the Little Bertha-Pathfinder claims, 12 miles north of Grand Forks.

A STOPE IN THE BLUE BELL MINE, AINSWORTH DIVISION, BRITISH COLUMBIA

This property is an amalgamation of the companies owning the Little Bertha and the Pathfinder properties, which adjoin. Years ago each property marketed considerable high-grade silver ore, the last shipments of which went to the Greenwood smelter in 1917.

FORT STEELE.—It is reported that the building of a concentrator at the Victor property on Mans creek, is about completed. This property has been under development by R. Abernethy, of Spokane, and associates. The ore is complex, containing argentiferous galena and zinc-blende associated with iron pyrite in a quartz gangue.

VANCOUVER.—Mining men are interested in a recent announcement from Ottawa to the effect that the silver content in Canadian silver coin has been reduced, an order having been passed that on and after January 1, 1920, coins shall contain 800 parts of fine silver and 200 of alloy. Sir Henry Drayton, Minister of Finance, states that this will bring Canadian coinage to the same level as that of many other countries and will discourage melting of silver coins for the sale of the metal.

ONTARIO

DOME MINES DOING WELL. — DECEMBER OUTPUT AT NIPISSING.

PORT CARP.—The Dome Mines has considerably increased its working force and has now about 350 men on the payroll. The mill is treating 950 tons of ore daily. The annual meeting in March is anticipated with considerable interest, as the important question of whether the company will exercise its option on the Dome Extension will be decided. Much depends on the result of diamond-drill operations now being undertaken to ascertain the downward continuation of the large orebody now being opened up on the 600-ft. level, which is said to be 100 ft. wide at one place with ore estimated to average \$5 per ton. Should the diamond-drilling from the 600-ft. level show that the orebody continues down to the 1150-ft. level a large tonnage will be proved. An important find has been made at the Davidson Consolidated, where a deposit of high-grade ore is stated to be 32 ft. wide has been cut in drifting on the 500-ft. level. Another orebody has been found on the 550-ft. level. The shaft on the Clifton is down 200 ft. and some good ore has been developed.

KIRKLAND LAKE.—The Wright-Hargreaves, which will resume operations in the spring, is transporting mill-machinery to the mine which will be installed as soon as the weather permits. The Teck Hughes mill is in steady operation treating about 80 tons per day. The Lake Shore has been completely unwatered and production is now normal. The Kirkland Combine, controlled by Chicago interests, has sunk a shaft to 75 ft. which will be continued to 200 ft. before a station will be cut. The vein continues good to the point reached.

LARDER LAKE.—At the Associated Gold Fields results from sampling and diamond-drilling tend to confirm the development of a good tonnage of ore. Operations are being actively carried on by a large force and the company has funds on hand to the amount of \$825,000. The deposit on the Harris Maxwell property, known as Block B, is stated to be 300 ft. wide. It has been cross-cut in four places on the 500-ft. level and is being explored at the 400-ft. level. The ore will be blocked out in 75-ft. sections. Two wide ore-shoots have been opened up together with a number of smaller ones in the 300-ft. dolomite formation. While it is hoped that the whole body will yield commercial ore, the policy in the meantime is to develop the two main shoots. The deposit on the Reddick and Kerr-Addison properties, which is 500 ft. wide, has been cross-cut in two places 1000 ft. apart, on the first level. Exploration by means of extensive diamond-drilling and underground work are stated to have proved-up this deposit for a distance of nearly a mile.

COBALT.—During December the Nipissing mine produced \$423,139, as compared with \$350,209 in November and \$375,217 in October, thus making a total of \$1,148,595 for the last quarter of 1919. This is the highest quarterly record for Nipissing. With costs averaging 40c. per ounce and with silver selling at \$1.30 the net profits amount to more than two-thirds of the value pro-

duced. Current net profits, therefore, are now at the rate of over \$3,000,000 annually, or more than 50% of the company's issued capital. During December the Kerr Lake mine produced 106,000 oz. of silver, the net value of which is estimated at \$150,000.

The McKinley-Darragh will endeavor to keep its oil-flotation plant operating all winter. It has been found that the pumps operate successfully through weather registering 30° below zero, and that the only danger lies in the possibility of an interruption in operation.

The Beaver Consolidated, in addition to meeting with renewed success in the development of its silver mine at Cobalt, is gradually strengthening its position through developing the Kirkland Lake Gold mines in which it holds close to 90% of the stock. The Beaver is realizing some \$2000 per day net profit on its Cobalt operation, while the mill of its Kirkland Lake mine is now operating at full capacity of 150 tons per day and yielding a substantial profit. Underground developments at the Kirkland Lake have recently been favorable, a shoot having been opened up in which a considerable quantity of ore is worth \$30 per ton.

SONORA

EXPORTS OF ORE.—NORTH TIGRE LEASING CO. IS ACTIVE.

AGUA PRIETA.—While bad weather has interfered materially with ore-shipments during the middle period of the month, it is believed that the value of export will be about the same as during December, despite the decreased tonnage. Some exceptionally rich ore is to be shipped. Las Chispas, which recently made a bonanza-strike on the 600-ft. level, sent out a carload of high-grade ore that assayed exceptionally well in silver. Eight small boxes, weighing about 140 lb. each, are said to have totaled approximately \$32,000. Three other cars of high-grade ore and concentrates passed through en route to the United States on the same day, and it was stated that the total shipment amounted to more than \$180,000.

EL TIGRE.—The North Tigre Leasing Co., operating the North Tigre mine, withdrew its low-priced stock from the market January 20 and it was announced that it will not be necessary to sell any more stock at present. The company now is amply financed and has a sufficient treasury reserve to ensure operation until returns from shipments are realized. A 50-ton mill, designed by Joseph Englund of Bisbee, which is intended to be the first unit of the plant, is expected to be in operation by February 15. It uses flotation in conjunction with wet-concentration and is expected to turn out 10 tons of concentrate per day, valued at not less than \$300 per ton, when in full operation. Electric power for mill and mine work is obtained from the power-line from the Copper Queen smelter at Douglas. Engineers' estimates are that more than 40,000 tons of ore has been blocked out in the mine, shown by assays to contain approximately 1,400,000 oz. of silver, besides copper and gold. Frank J. Holmes, manager, now is engaged in breaking down a supply of ore for the mill and in getting the mine workings in good condition.

THE MINING SUMMARY

ARIZONA

Patagonia.—Cross-cutting on the 260-ft. level of the Flux mine has opened up ore running \$30 per ton in silver and copper, at a point 300 ft. south of where it is expected to find the downward extension of the Glory Hole orebody. The cross-cut lacks 25 ft. of reaching the west contact. F. B. Kolberg is manager.

Tucson.—The Ohio Arizona Copper Co. situated in the Silverbell mountains has installed a tram-line from the mine to the road where loading-bins are to be constructed. Recent development has blocked out a large body of ore and shipments are to be commenced in the near future. —The Daily Arizona Copper Co. is now conducting tests preparatory to the installation of a flotation plant to treat the ore that has been blocked out by 2000 ft. of recent development work. A road is being built from the mine in the Santa Catalina mountains to Oracle 35 miles north of Tucson.

CALIFORNIA

Amador County.—Production at the Kennedy mine has been reduced as the result of a cave on the 4000-ft. level. A block of excellent ore 100 ft. long and three sets wide was being mined too rapidly, with the result that filling was neglected and the cave resulted. —Thirty stamps of the Central Eureka at Sutter Creek are dropping on ore from the 3300, 3500, and 3700-ft. levels. New ground is being opened. A small dividend was declared in December. —Sinking continues at the Old Eureka and ore of fair grade has been uncovered in old levels, but no attempt will be made at this time to extract it.

Grass Valley.—The Idaho-Maryland Co. has 80 men on its payroll and is reported to be preparing to prospect ground above the 500-ft. level. Arrangements are also being made to unwater the mine to a depth of 1000 ft. —New buildings have been constructed at the Central Consolidated, under the management of Paul W. Smith. Preparations are being completed for installation of hoisting and pumping equipment. John H. Nichol, general manager, states that a new process will be used in recovering gold from the refractory ores.

Nevada County.—The 5-stamp mill, compressor, black-smith shop, and other equipment on the Gold Canyon mine near Moore's Flat was recently destroyed by fire, entailing a loss of \$10,000. The property belongs to Mrs. F. Hill of San Francisco.

Sierra County.—The Tighten company at Alleghany has picked up the Star vein in a drift off the main tunnel. —A tunnel is being run by the Bessler brothers on their claim at the edge of the Downieville townsite for prospecting purposes.

COLORADO

Mayday.—The Jumbo Mining Co. is reported to have opened up a 5-ft. vein, the ore from which assays 25 oz. silver per ton. Two pack-trains are transporting the ore to the Mayday spur for shipment to the Durango smelter.

Ouray.—Luna and Eckman, lessees on the Wedge mines, have discovered a vein of high-grade silver ore, assaying

200 oz. per ton. At present prices the operators received good returns.

San Juan County. The Gnome Mining Co., operating the Columbus mine, has opened a new body of lead-zinc ore which is said to be the most important strike in that section for years. The vein, where it has just been intersected by a cross-cut tunnel 1500 ft. long, shows a width of 30 ft. of ore, which will average \$20 per ton. The vein also carries several heavy streaks of solid mineral which will run well in silver and gold, the two amounting to \$75 per ton. The cross-cut tunnel intersects the vein at a vertical depth of more than 700 ft. below the outcrop and thus furnishes a large territory from which to extract ore. Arthur W. Johnston is manager.

Silverton. —A find of good ore in Tunnel No. 4 is reported by the Gold King Extension Mines Co. W. Z. Kinney now has a strong financial backing, and if the present run of ore continues, the operations will no doubt be resumed upon a large scale. At the present time the mill is running one shift. —The Dives Leasing Co. is breaking some good silver ore in the Old Shenadoah. The snow conditions interfere with the packing of the ore to the railroad, so that the ore is being stored for later shipment. —The Southwest Mining Co. is working a force of 35 men on the Iowa-Tiger.

Telluride.—The Black Bear shaft is now down 300 ft. below No. 5 level. Drifting operations are under way from the bottom of the shaft, and also from No. 6 level, to intersect the vein at these depths. —The Tomboy Gold Mines Co., Ltd., is now operating the new mill treating 700 tons of ore daily. With the new process, there is a more satisfactory recovery of copper. —The Smuggler Union Mining Co. is now shipping heavily.

IDAH0

Clearwater.—The South Fork Mining & Milling Co., owning the South Fork mine in the locality of Ten Mile, has sold a block of treasury stock to Eastern capitalists for \$160,000 and will begin the erection of a mill in the spring, according to report.

Coeur d'Alene.—Fire destroyed the Bunker Hill & Sullivan North mill, or experimental plant, situated on the tailing dump immediately north of the East concentrator, on January 8. The mill is a total loss amounting to about \$95,000, partly covered by insurance. —The Amy Mining, Milling & Development Co. is cross-cutting from the bottom of a 200-ft. shaft to tap a vein that yielded ore on the tunnel level, according to M. J. Schermerhorn, a director of the company. The orebody is three feet wide on the tunnel level and the clean ore contains 60% lead and 12 oz. of silver per ton, according to the returns on three shipments.

Elmore County.—The Treasure Mines Co. has cut the first vein in its deep tunnel and is proceeding toward the second, which should be reached in March. In the upper workings of the mine ore blocked out has a value of \$200,000. The value is in gold and the ore mills freely.

Wallace.—The Consolidated Interstate-Callahan company shipped 3900 tons of zinc ore and 1100 tons of lead ore in

December. The zinc shipments were 1,800,000 lb. higher in December than in November. The grade of zinc concentrate is averaging more than 50%. The lead concentrate contains about 60% lead and 2 oz. of silver per ton.

NEVADA

Austin. The Nevada Birch Creek Co. reports that the Cahill lode has been intersected in the upper tunnel. The drift is said to be in a full face of shipping ore. From the dip of the vein it is believed the lower tunnel will pick up the orebody 125 ft. from present working face. This tunnel is in about 500 ft. J. T. Ingram is manager. The 1500-ft. drift from the 200-ft. level of the Austin-Dakota has intersected a shoot of ore said to assay from \$150 to \$500 in silver and gold.—The International Victory Co. is about to purchase a hoist and other equipment for its Yankee Blade property. Sulphides are appearing in the 60-ft. shaft on the Star of the West claim. The company is also planning to buy a motor-truck and to actively develop its holdings at Birch Creek. J. W. Schwebel is manager. — The Richardson and Hiawatha tunnels of the Austin Nevada Consolidated are showing ore containing silver and gold.

Kimberly.—Good progress is being made by the Consolidated Copper Mines Co. in sinking the Alpha shaft, which has now reached a depth of 1640 ft. A diamond-drill hole has just been completed at the extreme western end of the 1300-ft. level. This passed through 20 ft. of ore averaging 7.28% copper between the 1300 and 1400-ft. levels and a second body 65 ft. thick which averaged 7.1% copper. The bottom of this ore is at a depth of 1555 ft. Active development is also in progress at the Taylor mine on the north contact.

OREGON

Gold Hill.—F. H. Van Horn, representing Victor W. Brown and associates of Pittsburgh, Pennsylvania, has taken a lease and option to buy the old Sylvanite group of quartz-gold mines two miles north-east of Gold Hill. The property was recently operated by the Gold Hill Mines Co., of which J. W. Davies of Sacramento, California, is the head. It was closed down last summer, due to the scarcity of labor and the high cost of mining. Davies is now on the ground and announces that the lessees propose to resume as soon as they can repair the mine and mill equipment. The property has a 10-stamp mill and other machinery, driven by electric power. Considerable interest has been attached to this property since the discovery, in March 1916, of tungsten in the form of scheelite along with the gold ores. The mineral occurs in small stringers of quartz. Samples have been taken from these quartz veins which run as high as 40% tungstic acid, but it is said by the management that the vein as a whole runs less than 2%. The veins carrying the best grade of tungsten have been developed to only a small extent, but more work will be done.

WASHINGTON

Spokane.—Extensive preparations are being made for the annual Northwest Mining Convention which meets here February 16 to 21. The convention has come to be regarded as a most interesting and useful annual event by the mining people of Washington, Idaho, Oregon, Montana, and British Columbia. A comprehensive program is being arranged and a large attendance is expected.—Sinking has been in progress on the Olohim copper vein on the former Spokane Indian reservation, under the management of James Keeth of Spokane. Some copper ore has been shipped to the smelters. The construction of the State road to Detillion bridge will open the mineral-belt of the Spokane River valley north-west of Davenport, which is now producing copper, silver, tungsten, and coal in paying quantities. Transportation conditions have been the main drawback to the opening of this country.

Personal

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

F. C. Frey has gone to Mazatlan, Mexico.

R. B. Todd, of Reno, is in San Francisco.

Charles Butters has gone to San Salvador.

W. A. Meloche has returned from Mexico to Seattle.

E. K. Soper has returned to New York from Trinidad.

Augustus Locke is in the Christmas district of Arizona.

Ellsworth Daggett, of Salt Lake City, is at the Hotel Biltmore.

A. A. Boyd is manager of the Mount Morgan mine, in Australia.

Oscar Lachmund, of Spokane, was at Salt Lake City recently.

Eugene H. Dawson has returned to New York from Alaska.

F. Le Roi Thurmond has gone from Seattle to Swansea, Arizona.

Angus Mackay has gone from San Francisco to Butte, Montana.

Eugene Davis has returned from a visit of inspection to Eureka, Nevada.

H. R. Bostwick is at Yokohama; he is not expected in San Francisco until June.

Francis J. Heney is president of the Swisshelm Gold-Silver Co., at Tucson, Arizona.

Samuel J. Nasmith has returned from the Dolly Varden mine in British Columbia.

R. A. Grimes, of Sandon, B. C., has been in San Francisco for the purpose of testing a shipment of ore.

W. Mont Ferry is now managing director for the Silver King Coalition Mines Co., at Park City, Utah.

P. S. Janderup is constructing engineer for the Balbach Smelting & Refining Co., at Newark, New Jersey.

Ira B. Joralemon has become assistant general manager of the New Cornelia Copper Co.'s mine at Ajo, Arizona.

W. B. Bishop is smelter superintendent for the Granby Consolidated Mining, Smelting & Power Co., at Anyox, B. C.

Brokaw, Dixon, Donnelly, Garner & McKee have moved their offices from 120 Broadway to 90 West street, New York.

Charles W. Botsford and P. G. Spillsbury have returned from an examination of the Volcano mine at Stein's Pass, New Mexico.

Thomas M. Owens has been promoted from superintendent of mills to assistant manager for the Federal Mining & Smelting Co.

T. H. Jenks is leaving El Paso for the Texas and Louisiana oilfields, and expects to be in New York about February 1, care of the Institute.

D. D. Moffat, consulting engineer of mills, and E. W. Engelmann, consulting research engineer for the Jackling properties, are at McGill, Nevada.

R. G. Casey, of the Mount Morgan Gold Mining Co., in Queensland, has been investigating copper-leaching processes in this country; he is now at Victoria, B. C.

S. K. Dahl, who recently returned from a four years residence in South Africa, where as mill-superintendent he modeled and operated the Messina Transvaal Development Co.'s concentrating plant, has joined the firm of Otto Wartenweiler & Company, at Los Angeles.

THE METAL MARKET

METAL PRICES

San Francisco, January 20

Aluminum dust, cents per pound	65
Antimony, cents per pound	11.00
Copper, electrolytic, cents per pound	19.50
Lead, pig, cents per pound	8.75-9.75
Platinum, pure, per ounce	\$150
Platinum, 10% iridium, per ounce	\$180
Quicksilver, per flask of 75 lb.	\$300
Spelter, cents per pound	11.00
Zinc dust, cents per pound	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

January 20.—Copper is dull and easy. Lead is quiet and firm. Zinc is inactive and steady.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

Recent discussion regarding fall in reserve ratio of reserve banks to near the "danger limit" of 40% has led to a misunderstanding in certain quarters regarding the requirements in this particular. Ratio figures referred to recently are based on an arbitrary standard fixed by the Federal Reserve Board and constitute no legal requirement. The Federal Reserve law fixes two minima of reserves for reserve banks—35% of total cash reserves against net deposits and 40% gold against Federal Reserve notes outstanding. Some time ago, as a practical basis of operation, reserve banks adopted the ratio of total reserves to net deposits and Federal Reserve note liabilities combined, and recognized 40% as an arbitrary minimum to work from. To all intents, a rise or fall of this ratio portrays varying reserve conditions.

But reserve banks still observe the legal requirements of reserve and each week publish, in addition, the ratio of gold reserves to Federal Reserve notes in circulation, after setting aside 35% against net deposit liabilities. So long as the banks keep their gold reserves against notes outstanding above 40% they are conforming not only to the law but to the recognized standard of sound banking. Instead of a ratio around 40%, reserve banks, as a matter of fact, have been holding a ratio of gold reserve against notes around 50%. Last week the ratio stood at 49.5% for the entire system, compared with 42.7% of total reserves to net deposit and note liabilities combined. The New York Federal Reserve bank last week reported gold reserves against notes as 42.4%, compared with the break below the arbitrary minimum, to 38.7% on total reserves against net deposits and notes combined.

While the ratio of gold reserves is thus above the legal minimum, a larger decline has taken place in this ratio over the past year than in ratio of total reserves to net deposit and note liabilities combined. In the twelve-month period, gold ratio of the entire system has fallen 11.3 points, as compared with 7.4 points in total reserves against combined liabilities, and for New York Federal bank the declines have been 39.5 and 9.6 points, respectively. Loss of gold is mainly responsible, which, in the case of New York, amounted to \$111,144,000. At the same time there has been a big expansion in note circulation, as shown below:

Combined System

	Dec. 26, 1919	Jan. 2, 1919
Total gold reserve	\$278,332,000	\$299,194,000
Federal Reserve notes outstanding	3,057,646,000	2,647,654,000

New York Federal Reserve Bank

	\$570,438,000	\$686,208,000
Total gold reserves		
Federal Reserve notes outstanding	821,944,000	724,032,000

The loss of gold was largely, if not entirely, due to exports out of the country, which last year exceeded imports by over \$270,000,000. If this movement continues, without corresponding contraction in note liability, it will not be long before legal reserve ratio declines to the danger point. By that time, however, the Federal Reserve Board is expected to put its corrective machinery in operation, in shape of higher discount rates. How far these measures will be effective in checking outward movement of gold is one of the interesting banking problems before the country.

Foreign exchange quotations on January 20 are as follows:

Sterling, dollars; Cable	3.69 1/4
France, cents; Demand	3.48 1/4
Paris, cents; Demand	8.60
Lire, cents; Demand	7.30
Marks, cents	1.80

Eastern Metal Market

New York, January 14.

The markets do not exhibit the tendency toward wild speculation that was the feature a week ago. While demand is good it is quieter and prices in most cases are firm.

Following the heavy demand for copper during the past few weeks inquiry is not so heavy and prices are slightly lower.

Tin prices have been erratic and are again higher with heavy sales last week.

The lead market is quieter but very strong with supply still unequal to demand.

Demand for zinc, especially from foreign sources, is lighter and the market is quieter with prices a little easier.

Antimony is in better demand and considerably higher.

IRON AND STEEL

New evidence is afforded in the steel market of the large volume of unsatisfied demand and of the advancing tendency in all products in spite of the Steel Corporation's large sales at 'pegged' prices. The gain by the Corporation in unfilled orders for December amounting to 1,137,036 tons is in strong contrast to the condition of most of the independents, some of whom refrain from quoting beyond the first quarter. The calling off of the steel strike means only a little improvement in labor supply. Because of labor shortage and lack of efficiency, scarcely more than 75 to 80% operation for most plants is likely before the middle of the year, with some falling short of that now. New orders for rails continue to be placed and Eastern plate-mills have had before them in the last week about 250,000 tons in inquiries, of which 150,000 tons is for shipbuilding. There is no let up on the advance in British steel prices with all lines up generally from \$2 to over \$9 per ton.

COPPER

The market is quiet; demand is still good but lighter. This is a natural consequence of the heavy buying which appeared in November and December, particularly in December. It is now stated that December business was the "largest ever recorded in the history of copper excepting perhaps certain months during the War when blocks of copper of phenomenal size were negotiated by certain foreign governments". Some place the December business at 500,000,000 lb. Quotations are a little easier at 19.25c., New York, for electrolytic for January and first quarter delivery and 19.50c. for Lake. While stocks in the hands of producers continue large, they are diminishing, but both stocks and production are still in excess of demand. Export demand is good, and somewhat higher prices are said to be realized than on domestic orders.

TIN

The tin market continues to be largely controlled by the British speculative situation. There, values have continued to fluctuate but mostly to advance until yesterday spot Straits was quoted at £379 10s. per ton, an increase of £15 10s. over the quotation a week ago. In the last few weeks or since November 5 the London market has advanced nearly £100 per ton. There was a slight recession in values here the latter part of last week which resulted in heavy buying which on June 8 totaled about 1000 tons. The transactions ranged at from 60.25 to 61.75c., New York, the average being 61c., and this consisted of sellers taking profits, and substantial ones too, on metal bought some weeks ago at around 52.50 to 55c. per lb. Large and small consumers were buyers as well as some dealers. Yesterday, as a result of higher British prices, spot Straits was quoted at 65c., New York. There is some uncertainty whether large

consumers or consumers in general are well covered for future needs. It is possible that they are better provided for than is suspected but only the extent of the usual spring buying movement will reveal the true situation. Arrivals of metal so far this month have been 950 tons, of which 240 is credited to Pacific ports; 7370 tons is reported afloat.

LEAD

From appearances heavy demand is letting up and the market is quieter. The American Smelting & Refining Co. advanced its price on Wednesday 1c. to \$2.25c., New York, or 8c., St. Louis, but the outside market continues far in advance with prices very firm. Spot-lead is still exceedingly difficult to obtain and the quoting of a nearby market is difficult. Opinions vary, some claiming that this position is at least 9c., New York. It is probable that the bottom is not less than 8.75c., New York, with a fair appraisal at 8.87c., New York, or 8.62c., St. Louis, which we quote as the market. Some buying for export of lead in bond is reported.

ZINC

This market is much quieter than last week, due to a let-down in speculative activity in London. Values here continue to follow largely the fluctuations in that market, the principal demand coming from that quarter. There has been an easing in British prices and a consequent slight decline here, values fluctuating mildly each day. Prime Western for early or first quarter delivery is quoted at about 9.37c., St. Louis, or 9.72c., New York, with demand fair. It is acknowledged that buying for export, particularly by England, has been very heavy in the last few weeks. Domestic demand continues light. Galvanizers are only partially covered, having some stocks unused because of the steel and coal strikes. They will, however, undoubtedly be heavy buyers soon.

ANTIMONY

The market is much stronger on better demand and diminished supply. Reports from China are that supplies are hard to obtain for export. Wholesale lots, five tons and larger, are quoted at 10.25c., New York, duty paid, for early delivery, with jobbing lots about 11c., New York, duty paid.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted at \$1.50 to \$2.50c., New York, for wholesale lots for early delivery.

ORES

Tungsten: Until the tariff matter is settled there seems very little prospect of much business and a settlement of this question by the Senate seems far-off. The market is very dull as a consequence and quotations are largely nominal at \$7 to \$15 per unit in regular concentrates. Some Chinese ore is reported sold in the last week at \$6.50. Ferro-tungsten is nominally quoted at \$1 to \$1.15 per lb. of contained metal.

Molybdenum: A small business is reported at the prevailing prices of around 75c. per lb. of MoS₂ in regular concentrates.

Manganese: The market is strong and ores are scarce. It is stated that American makers of ferro-manganese are now willing to pay 75 to 80c. per unit. Imports in November are returned as only about 11,000 tons, the smallest of any month for the year.

Manganese-Iron Alloys: Ferro-manganese continues to advance and supplies are not more plentiful. Almost no domestic alloy is procurable for first half; only small lots for spot delivery are reported for which \$175 to \$180, delivered, is asked. Even low-grade alloy, 70%, is held at \$150, delivered, for spot.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE DEVELOPMENT OF THE ROCK-DRILL IN AMERICA

By Charles Austin Hirschberg

*In 1879 the discovery of the lead-carbonate silver ores of Leadville gave renewed impetus to the mining development in Colorado. It was about this time that the miner put aside his single-hand hammer and steel in favor of the power rock-drill, invented by J. J. Couch of Philadelphia in 1849 and perfected during the intervening years by Couch and J. W. Fowle of Boston, patent rights finally being purchased by Charles Burleigh about 1866. The Burleigh drill was used in driving the Hoosac tunnel in the year 1867.

In 1871 another power-drill was invented by Simon Ingersoll,

Fig. 1. The Couch Rock-Drill. The First Power Drill

soll, and other similar drills, such as those of Wood, Sergeant, Waring, Halsey, and Githens, made their appearance.

From this time on, the primitive methods of mining gave way rapidly to the so-called reciprocating-piston rock-drill, which comprised a cylinder carrying a piston with a projecting end, to which the drill-steel was fastened rigidly.

The year 1894 marked another stage of progress. It was then that J. George Leyner, a native of Colorado, born in Boulder county, opened his small machine shop in the city of Denver, for the repair of mining machinery. This enterprise led him into numerous experiments with the power rock-drill, culminating in the invention of the first hammer-drill about 1897, a type in which the piston moves freely in the cylinder and strikes upon the drill-steel instead of being attached fixedly to it, and pushing it as in the reciprocating type of drill, a direct reversion to the principle involved in the primitive method of hammering the drill by hand.

There is no questioning the debt the mining industry owes to the invention of the reciprocating type of rock-drill, but it remained for a Western man, Mr. Leyner, born in a mining community, to make this scientific step in the

art of drilling rock. No need to dilate at length upon the things he accomplished in the invention and development of the hammer-drill, such as the introduction of water and air through hollow-drill steel for cleaning the hole,

Fig. 2. Showing From Top to Bottom: 1. Fowle's First Rock-Drill. 2. The Burleigh Drill Used in Hoosac Tunnel. 3. The Wood Drill. 4. The Ingersoll Eclipse Drill. 5. Leyner's Hammer-Drill of 1897. 6. Leyner's Drill of 1898.

automatic lubrication, throttle-control enclosed in the machine, mechanical rifle-bar-rotating drill-steel chuck. All hammer-drills of the present day, irrespective of maker, have borrowed important features from the Leyner machine.

In testimony to the correctness of his theories, his business grew to a point where in 1905 he was forced to build a modern manufacturing plant at Littleton, Colorado, to take care of a rapidly growing enterprise, ending in the purchase of license rights by the Ingersoll-Rand Co. of New York, since which time further modifications and refine-

*Published by courtesy of 'Compressed Air Magazine'.

ments have been made, as typified in the Leyner-Ingersoll drill.

Still another product of Colorado's inventive genius is the creation of the stoper-drill, which depends for its success upon an air-feed attachment to a drill-cylinder, first experimented with by C. H. Shaw of the C. H. Shaw Pneumatic Tool Co., at Denver, in 1906, followed rapidly by the Waugh slugger, also an air-feed type of machine, then the Crown air-feed drill of the Ingersoll-Rand, the Hardscog

product, followed rapidly by such machines as the Sullivan hand-hammer drill, the Hardscog Little Wonder, the Cleveland hand-drill, Leyner Brownie, and numerous others.

In the year 1909 the first real self-rotated hand-hammer drill made its appearance. Following the practice of making drills out of stopers, Mr. Leyner conducted extensive experiments with a Leyner drill-cylinder removed from its shell. He placed a T handle at the back with handles part-

Fig. 3. Side-Rod Construction

Wonder rock-drill, the Sullivan, the Cleveland, the Leyner stoper, and the Chicago.

These inventions were the progenitors of other styles of

way down the cylinder. He built several of these machines, more particularly for shaft-sinking. However, before he had gone far the Ingersoll-Rand Co. obtained a license to manufacture and sell under the Leyner patents, and as

early as 1912 the Jackhammer, the first self-rotating hand-hammer drill employing Leyner rifle-bar and sleeve-chuck rotation, was placed on the market. It proved such a success that other manufacturers brought out modified designs.

We often hear it said that there is nothing new under the sun. To some extent this saying may be applied to

Fig. 4. Cross-Section of No. 5 Water-Leyner

nammer-drills; in fact, the latter may be termed modifications of these first types. For instance, the majority of the early hand-hammer drills (excepting plug-drills, employed for drilling shallow holes in granite and stone) were largely patterned after the air-feed stoper, the air-feed being eliminated and a spade-handle substituted; indeed, the manufacturers of these early stopers advertised the interchangeability of handle and air-feed as a useful feature.

This early practice of interchangeability was, however, soon abandoned, for while good in theory it proved impracticable. Then came the Little Jap drill, an Ingersoll-Rand

present-day drill designs. Things that had been tried and tested in the early struggle with reciprocating drills, and later with the first Leyner drills, but abandoned because of their failure to perform as expected, and again in the latter case, because of the impossibility of securing suitable material and a lack of knowledge in those days of refined methods of heat-treating to enable material to stand up under the particular work they were to perform, are today making their appearance in the designs of many drills and are exploited as new.

Referring to Fig. 2, this shows the first reciprocating

rock-drill, as used by Burleigh in driving the Hoosac tunnel in 1867, a project fathered by the State of Massachusetts. The tunnel was five miles long, driven through hard rock. It was an ambitious scheme for those days, involving at its start the employment of hand-drilling. That the work in driving this tunnel was carried to a successful conclusion was largely due to the efforts of J. W. Fowle of Boston, who invented the Burleigh rock-drill. Burleigh's part in the development of this first drill rested with certain improve-

Fig. 7. Hammer-Drill Rotation-Mechanism

ments that he made as a mechanic in the shops of the Fitchburg machine-works, where the drill was built.

The Wood drill, shown in Fig. 2, was brought out shortly after the Burleigh drill had been used in the Hoosac tunnel. In the testimony before the Massachusetts legislature appears the following statement: "We were satisfied that this drill was an entire infringement on Mr. Burleigh's patents, and that our obligations to Mr. Burleigh ought not allow us to suffer the Michigan drill (Wood) to be used by our contractors."

Next came the Ingersoll drill, first used in 1871. This employed a tappet-valve action and followed somewhat new lines of design in that it utilized a guide-shell with feed-screw for feeding the machine forward, making it much

Fig. 2 shows the Ingersoll Eclipse air-thrown valve drill, which was an improvement over the Ingersoll drill invented by Henry C. Sergeant in 1873 and brought to its final state of development in 1878. This was the first independent valve-motion control. The Ingersoll Eclipse drill was employed in driving such tunnels as the Cascade, Bozeman, Silverbow, Siskiyou, Snow Shoe, Vosburg, Coosa Mountain, Wickes, and the Croton aqueduct.

In the meantime the Sluiger rock-drill was invented by Halsey and introduced by the Rand Drill Co., now the Ingersoll-Rand Co., in 1883. This machine, it will be noted, is equipped with side rods and a flat back-head spring to absorb shocks. The valve is of the piston or spool type. While having an independent valve action it was without variable stroke. It was largely used in mine work and in some of the big aqueduct-tunnels.

A great many of our modern drills employ independent air-thrown valve-actions patterned largely after these two first types. Even the first Leyner hammer-drill borrowed the spool valve from these early constructions. Fig. 4 shows the valve action of a number of makes.

In 1884 the Sergeant auxiliary-valve drill came to the front, bringing with it the release rotation and a spool-valve motion controlled by a crescent-shaped piece in contact with the main piston. This type of drill largely replaced the Little Giant in the Lake Superior mines and drove the Catskill aqueduct-tunnels and many others, among them the Pennsylvania tunnel under the East River, New York. The release rotation feature of this type of drill gradually found its way into other makes of drill, including the No. 6 Water Leyner drill brought out by Leyner in 1906.

Starting about 1899 up to the present time we pass through a revolution in the mechanics of the rock-drill. This is the period of hammer-drills and we see the gradual passing of the piston-drill. Leyner's drill as shown in Fig. 2 made its appearance in 1897, followed by the type of drill shown in Fig. 2, in 1898, it being the first of his or any other drill to employ water and air through the drill-stem.

Referring to Fig. 5 we find present-day builders of hammer-drills borrowing in its essential details the water

Fig. 8. Throttles and Front-Heads

lighter and, therefore, possible to mount on a so-called bar in placing of a carriage. It was employed in the Musconetcong tunnel of the Lehigh Valley Railroad.

The Rand Little Giant drill was subsequently developed by A. C. Rand and George Githens in 1875. This also employed a tappet-valve action controlled by the motion of the piston to operate the valve. It was with this type of machine that the side-rod construction made its appearance, which is found even today in later drills, such as the present-day Leyner-Ingersoll, the Sullivan water-drill, the Sullivan piston-drill, the Denver Dreadnaught, and many others. See Fig. 3.

The Rand Little Giant drill was largely adopted throughout the Lake Superior iron country as well as certain parts of the copper country. Some of its notable work is the Hell Gate channel excavation and the Weehawken tunnels.

and air principle of the Leyner drill. Fig. 6 illustrates the No. 5 Leyner drill brought out about 1903, showing substantially the same type of rotation first employed in the later models of Leyner drills, except that it had a locking key for holding the steel in the chuck, which feature was abandoned in the Model 6, already referred to, and later types.

Fig. 7 shows the rotations of various makes of hammer-drills, which it will be noted correspond in main essentials to the Leyner type. The No. 7 Leyner drill may be said to be the real father of all existing hammer-drills. It includes in its design the Sergeant release-rotation feature, the rifle-bar rotating sleeve-chuck feature, the water and air feature, and the first automatic lubricator, as well as the enclosed machine-throttle construction, and one-piece solid-front head and finally, split-front head with through-bolt retained front-

head cap. It is interesting to note the variations of features of these designs as found in other makes of machines, as shown in Fig. 8, including the mounted hammer-drills, self-rotating hand hammer drills and stoper drills with their air-feed attachments as well.

It is interesting to compare the advance that has been

made in the self-rotating hand-hammer drill, starting with Leyner's first experimental machine constructed in 1909, on through to the Ingersoll-Rand Co.'s various Jackhammer types, Sullivan Rotator, Denver Rock Drill Co.'s Clipper drill, Chicago Pneumatic Co.'s Hammer, McKiernan-Terry, Busy Bee, and many others, as shown in Fig. 9.

THE Northwest Mining Convention will meet at Spokane on February 16 and the five following days.

WE have received a contribution to discussion signed 'Claimant'. The writer of it has failed to give his name and address. We do not publish anonymous communications; it is an unwritten rule in respectable journalism to disregard such letters. The name of the sender must be given, even though the writing itself is published under a pseudonym. Usually we prefer to publish letters from those who are willing to fight in the open.

IT is reported from Washington that the Committee on Mines and Mining of the House of Representatives has been holding hearings on the legislation proposed for liberalizing the War Minerals Relief Act. Witnesses from all parts of the country have been heard and the Committee has shown keen interest in the matter. Meanwhile a few claims have been settled, most of them after amputation, and some measure of progress is being made by the Commission.

NEW gold from South Africa is being sold in London at a premium fluctuating between 20 and 25%, as previously recorded in these columns, but payment is made in pounds sterling, which have depreciated 24%; in short, the appreciation of gold and the depreciation of sterling exchange are complementary, and parts of the same process of economic adjustment. The market-value of South African gold has not risen in terms of the dollar. However, the mining companies on the Rand pay for labor and supplies in British currency, so they obtain the full benefit of the premium on gold as paid in their market, which is London. Here we may note that the Mount Morgan Gold Mining Company is selling its gold in China at a premium of 33%. This likewise represents the fall in sterling exchange.

HEARST is out against Hoover. That should commend the latter to the American people. Senator Reed, who made himself notorious by his malicious attacks on the Food Administrator, fills three columns of Hearst's local newspaper with a tissue of lies and absurdities. One can hardly imagine greater misuse of public money than the printing of an article from Hearst's New York 'American' in the Congressional Record; yet that was done, on the request of Mr. Reed. Hearst's scribe says that "no member of the Senate

thought well enough of Hoover's candidacy to rise and defend him from Senator Reed's attack". There was an obvious reason for ignoring it. It is regrettable that the Senate, when so much important public business is pressing, should allow its time to be wasted by pothouse talk.

STOCKS of copper are being liquidated, thanks to an increase in domestic consumption and better buying from abroad. During January several large sales were made; and if the price remains quiet, it is due mainly to the fact that those in control desire to free the market from big unsold accounts. Lead is in demand for domestic consumption. The stock of this metal in British hands amounts to about 300,000 tons, and the British government seems disinclined to part with it, thereby maintaining a menace to the market.

NICKEL coinage is being urged upon Canada, and among its advocates is Dr. Willet G. Miller. He summarizes his argument thus: "Nickel is the most durable metal for minor coins; it cannot be successfully counterfeited, and it can be called Canada's national metal, since this country produces over 80% of the world's output." Fifty countries, he says, use coins made of pure nickel or nickel alloys, and in this respect the British dominions are exceptional in using none. The American 'nickel' contains 75% copper; it is not as attractive as the similar coins made of pure nickel. There seems room for the use of more of this metal for minor coins in Canada, but in the United States we shall continue to favor our own products, copper and silver. In our last issue we noted the fact that the Canadian government, beginning with January 1, has reduced the fineness of its silver coins from 925 to 800.

GEOLGY as a science is suffering in dignity by reason of the use made of it in mining litigation. This is the subject of a vigorous article, on another page, by Mr. Augustus Locke, a mining engineer whose experience and reputation give value to his remarks. He is frank in his utterance, but, of course, without personal antagonism toward any of the worthy gentlemen whom indirectly he criticizes. It is the custom, not the men, that excites his animadversion. We, like Mr. Locke, would like to see the same men engaged by the courts, instead of the litigants, to give testimony on the intricate questions of structural geology upon which the decision of apex-suits mainly depends. If they were to testify as impartial

observers, the lawsuits would be expedited and rendered less fortuitous in their results, but the greater gain to the mining industry would be the accumulation of accurate information concerning the structure and distribution of ore deposits. Science, as well as justice, would be clarified, instead, as now, of being confused by partisan testimony.

ECONOMIC problems are in the foreground of the national life of the Australian commonwealth as in our own country; therefore a description of conditions there, as they affect the mining industry, will be found interesting at this time. We publish an article by Mr. F. H. Bathurst, a veteran journalist, formerly mining editor of the Melbourne "Argus", one of the great papers of the English-speaking world. It will be noted that in the effort made by the Australians to rid themselves of the German metal octopus, they established a Metal Exchange for the registration of sales and contracts between the producers and the dealers in metals. This proved beneficial in many ways, although it did not fulfil the utmost dreams of its organizers, because there remained the jealousy between the financial groups controlling the mines. Undoubtedly the mining industry of the United States, and of the American continent as a whole, would be benefited by the establishment of a Metal Exchange in New York. At present the fixation of prices is too much of a 'trust' affair, and therefore rightly arouses suspicion on the part of the mining public.

THE 'Engineering and Mining Journal' announces the final severance of Mr. W. R. Ingalls' connection with that paper. He ceased to be responsible editor nearly a year ago, but since then, under the title of 'consulting editor', he has continued to prepare the metal averages. His resignation is an event in technical journalism, for Mr. Ingalls became editor of our contemporary in 1905 and has performed his duties with characteristic conscientiousness and thoroughness. His knowledge of the metal trades is unique and will be sorely missed by the publishers of the New York periodical. We have always questioned the accuracy of the average prices as compiled by Mr. Ingalls, simply because it is beyond the wit of man to arrive at correct figures in default of a complete record of sales, but he made a good effort to ascertain the facts, and we think it extremely unlikely that anybody less well-informed has any chance of achieving even his moiety of reliability. What New York needs is a Metal Exchange, on which all the sales are made and duly registered. As it is now, the attempt to impose the quotations of the 'Engineering and Mining Journal' on the industry is an absurdity, the reality of which is likely to be better appreciated now that Mr. Ingalls is no longer able to give them even the simulacrum of accuracy.

AMONG geological formations worthy of notice is one in the Silverton district. In a paper published at Tonopah, Nevada, we read: "The formation is rhyolite and lime, being the oldest in history—so old that no books

are available on the subject." The Silverton district was formerly known as Monte Carlo; it is not the Silverton in Colorado, where only the normal, modern, well-behaved, eminently respectable kind of rock formation is to be found. In its Nevadan namesake evidently there has been a geologic débâcle, a petrographic catastrophe, of the most subversive kind, bringing to surface a rock that has hitherto escaped the writers of textbooks. But why should the age of a rock render it immune from literary treatment? Some of the books published in 1919 describe rocks that were formed in 100,000,000 B. C. Nothing can escape the rock-sharp, not even the most antediluvian, prehistoric, primordial of limestones or rhyolites. We would like to hear more about it from our Tonopah contemporary. The formation is distinguished by enclosing or exposing "eight different groups" of "mineral finds" all of which owe their newspaper existence to the energetic exploratory work of Mr. Joe Tognoni, "the father of the district". A report has been made by a Mr. McSherry. Well, Tognoni suggests Chianti and McSherry recalls Amontillado, so here perhaps we find explanation for a certain inebriation of language, such as recalls the days gone-by, in that remote past before January 17. It is most interesting. The mining claims constitute an "estate", the veins are "most prolific", "a number of big deals are pending", and "several mining engineers, representatives of powerful financial interests in the East, have been examining the properties for the last several days". It sounds so familiar—all except the super-ancient rocks. That is a new touch. Put on another record, Mr. Promoter!

FRAUDULENT finance was fitly punished in the Pandolfo case by the 10-year sentence passed upon the irresponsible promoter of the Pan Motor Company. In that get-rich-quick affair it was shown how much such pirates depend upon a subservient press for their campaign upon the pockets of the unwary. Judge Landis condemned seathingly the editor of the Minneapolis 'News' and other newspapers that allowed Pandolfo's lying advertisements to masquerade either as news items or as special articles. The motor trade today is corrupting journalism by means of 'write-ups' not easily spotted by the unsophisticated. Readers of technical papers have good reason to resent their being served with articles that pretend to be unbiased but are furnished by the agents of manufacturers. We recognize that such articles have some value, but they are subject to discount, and the reader is entitled to know their source so that he may fix the rate of discount he sees fit. We have established a department at the end of our reading pages to which the name of 'Industrial Progress' is given. Under this heading it is stated that the information contained in the pages so designated is "furnished by manufacturers". Recently we have published two articles, on machine-drills and air-compression, furnished by two rival firms, and we have been amused to find these articles appearing in the body of our New York contemporary as if they were the writings of independent technicians. By plac-

ing 'Industrial Progress' between the last reading pages and the advertising pages, we indicate that it partakes of the character of both; it is useful information contributed by those in the trade. The average man hates to be deceived; to foist an advertisement upon him in the guise of ordinary reading-matter undermines his confidence in the editor. Such loss of confidence will cause him to abstain from reading the publication, thereby diminishing its value as a medium of publicity. Every misplaced write-up is an injury not to the readers only, but to the advertisers as well, because it entails a loss of effective publicity.

EUREKA is a Nevadan mining district that has not only yielded some 50 millions of dollars since the first work was done in 1873, but it is one that has been made famous by Monograph VII of the U. S. Geological Survey. 'The Silver-Lead Deposits of Eureka', by J. S. Curtis, was published in 1884 and has remained since then one of the most interesting applications of the science of geology to the art of mining. Among the richest mines in this district, or county, were the Richmond and Eureka, two adjacent properties owned by two companies that, in 1877, engaged in a lawsuit, which became celebrated as the forerunner of many apex litigations and the incubator of a new definition of the term 'lode'. These two mines are credited with a joint production of \$34,600,000. In 1905 they were consolidated under the control of the United States Smelting, Refining & Mining Co., on the initiative of the late Albert F. Holden. His death in 1913 and a quarrel with the minority shareholders contributed to the failure of this attempt to resuscitate an old enterprise, which has now passed into the hands of the Mining & Development Corporation of New York. Mr. Edwin O. Holter is president; Messrs. Harold Kingsmill and H. P. Henderson are the advisory engineers. They have organized a company called the Ruby Hill Development Company, for the purpose of exploring the lower workings of the Eureka-Richmond mines on Ruby Hill. No stock is being sold; we understand that the enterprise is of a private nature and that it is backed by several wealthy men connected with the Cerro de Pasco. The chief aim of exploration is to search for ore in the deeper ground beyond, or northeast of, the Ruby Hill fault, which limited the ore on the hanging-wall side of the workings above the twelfth level. The main, or Locan, shaft was re-timbered to this point by the U. S. Smelting company and the water-level now stands at 85 feet below it. Mr. J. H. Mackenzie was in charge of the pumps when in 1890 the management was struggling with a sudden influx of water; he had reached the 1200-ft. level when orders were received to cease work. He is quoted as having expressed a favorable opinion in regard to the prospects of finding ore on that level, which penetrates beyond the fault. To prevent confusion, it is necessary to state that the 12th level of the old workings is 450 feet above the 1200-ft. level from the Locan shaft. The report by Mr. Henderson on the geological structure is conservative. The chance of the

new company making a success where its predecessors failed depends largely upon the more effective machinery and cheaper power now available. It is a genuine adventure on the part of men well able to take the risks and competent to minimize them by the application of experience. We wish them good luck.

Hoover for President

The mining profession has a special reason for interest in this subject; since we wrote on the presidential campaign in our last issue it has become evident that Mr. Hoover, without any action on his own part, is being considered all over the country as a probable nominee. A strong undertow of sentiment is apparent both in conversation and in the newspapers in favor of the man who, next to President Wilson, caught the imagination and won the confidence of the American public during the heroic years of the Great War. Mr. Wilson lost it, in part owing to his own blunders, in part owing to the course of events, which introduced the venom of party politics into the discussions over the Treaty of Peace. Indeed, President Wilson's fall from the pinnacle of fame and popularity, at home and abroad, is extraordinary; the undermining of his personal ascendancy, the discomfiture of his plans, the breakdown of his health have brought about a collapse that in its completeness has the elements of a Greek tragedy. Only a mean man can derive any pleasure in contemplating it, and the pathetic consequences of it. On the other hand, his loyal coadjutor, Mr. Hoover, has escaped from the débâcle because he is less self-centred, less of an egoist, and better able, thanks to his training and experience, to make the most of the assistance placed at his command for the national service by a staff of clever men. It is the mark of generalship to be able to select good captains. Mr. Hoover has that characteristic, and its corollary also, namely, the ability to stimulate the powers of those who work with him. This is proved by the record of the Food Administration, as also by his later operations for relief in Europe. It is not surprising therefore that at this moment, unintentionally, he possesses a national organization eager for the chance to work in his behalf as a presidential candidate, for every member of the Food Administration would rally to the call of the Chief in an instant, should occasion arise, as seems now so likely. More than that, the Food Administration did good work; the men and women of this country know that it did; they complied with its regulations because the Food Administrator early gave the impression that he knew what he was doing; he was sagacious as well as humane. Thousands are eager to vote for him in total disregard of party ties. Every politician is keenly aware already that Mr. Hoover is the one man that can attract votes from the opposite party, whichever should nominate him. The New York 'World', a Democratic newspaper, has declared that it will be glad to support Mr. Hoover "as an independent candidate on a platform of progressive liberalism", adding: "We should not hesitate to support him as a Republican candidate on

a platform representing the kind of government which Hoover has exemplified in his public career." On the other side, many Republicans are saying that they will support him even if nominated by the Democrats. Party politics is in bad odor; the performances in Congress have sickened thoughtful men; the sacrifice of vital interests to partisanship has been too flagrant. There is a great work of reconstruction to be done during the next four or five years, and it will need the leadership of a man built on a scale of twelve inches to the foot. Most of the men named for the Presidency are political cordwood, not presidential timber; before June arrives they will be weighed and found wanting. Meanwhile Mr. Hoover is not a candidate; he has taken no steps to place his name before either party; not even his personal friends have been asked to make an effort in his behalf; anything that is being done is spontaneous. He stands aside as yet, not anxious for the call, but, like a good citizen, ready to obey if it have the authentic note of patriotic duty. He admired and supported Roosevelt; he admired and assisted President Wilson at a time when it was every American's bounden duty to rally to the Chief Executive; he is a liberal, a man of progressive ideas, a practical humanitarian, a just man, able to recognize the rights and wrongs of the economic struggle, but neither a mollycoddle nor a pussyfoot; he has seen enough of foreign ways to appreciate American ideals the more; he is the exponent of a virile Americanism that stands between the gushing internationalism of Woodrow Wilson and the frothy provincialism of Hiram Johnson. Gentlemen of the mining profession, let us elect him!

Intervention in Mexico

On another page we publish a letter from a mining engineer in Mexico on the subject of government in that distressful country. It contains much interesting information. The word 'Mexican', as an ethnologic term, is much misunderstood; so is the use of 'Latin America'. Most of the countries south of us are peopled by their aboriginal population, together with a relatively small admixture of those of European, chiefly Spanish, blood. In Mexico itself there are barely a million persons of undiluted Spanish ancestry; a large proportion of the half-breeds like to call themselves 'Spanish', but the people of Mexico are 75% Indian and 85% illiterate. Out of a population of about 16 millions, 6 millions do not speak the official language of the country; instead they have fifty different languages and innumerable dialects of their own. This is not the kind of stock that it is advisable to add to the 'melting-pot' on this side of the Rio Grande. The problem arising from our contiguity to Mexico is one that should receive the most serious investigation. As yet it has been tackled in a desultory and irresponsible manner. 'Watchful waiting' aided by such interpreters as Messrs. John Lind and Lincoln Steffens is not a satisfactory solution of the difficulty. The destiny of the United States hinges so largely on its treatment of the Mexican people that it would seem the

part of wisdom to appoint a commission of competent men to study the subject and report upon it, so that a national policy may be adopted, one that both political parties will agree to accept. To make our attitude toward Mexico merely the reflex of our own partisan politics is manifestly childish, because it will affect generations unborn. On account of our interest in the mining industry of Mexico, that is to say, our desire to see American exploitation in that country rendered safe and successful, we wish greatly that amicable relations may be established as a preliminary to the restoration of law and order, particularly in those remote localities where the mines are mostly situated; but there is more at stake than the welfare of American mining enterprise in Mexico. The welfare of the United States is at stake. If military intervention were forced upon us, either by Mexican action or by Hearst's yellow journalism, we would have to occupy the country, and possibly, in the end, annex it. There lies the danger. To add 12 millions of Indians to 10 millions of negroes would introduce a factor highly dangerous to our civilization. Already the stock that leavened the American people, and gave it the strong character reflected in its institutions during the 144 years of its national life, has been diluted, if not corrupted, by an influx of the poorer racial stocks brought to this country in an effort to obtain a sufficiency of cheap labor. The birth-rate of those of early American descent is small, and it is decreasing; that of the horde of uneducated immigrants is high, and it is maintained. The negro is prolific; so are the peons of Mexico. It is written in history that the lower breeds multiply at the expense of the higher; the outposts of Spanish civilization were swamped by miscegenation. The white people of the United States are trying to develop a high type of civilization, one based upon representative government; they are endeavoring to assimilate the diverse alien elements constantly arriving from Europe; they are hoping to create an American stock worthy of the fathers of this republic; is the greatest experiment in political chemistry to be spoiled by introducing reagents known to be of adverse composition; is the dream of an American nation to be made a nightmare of intermingled litters—yellow, brown, and black? It behooves us to face the facts with sober mind. The mere drifting called 'watchful waiting' leads nowhere; it is a negation of policy liable at any moment to be swept aside by popular clamor or private intrigue. For military intervention, without some well-thought purpose, wise and humane, the American people have no fancy. Pacifism is now deeply ingrained in the national spirit; this generation at least has had enough of war. There remains only a policy that will help the decent elements in Mexico to restore order, by aid of our moral support, backed by food and money, not by an army. All that we have a right to ask is that the Mexican government will observe its own constitution and laws; we should not try to impose our ideas of what is lawful; the restoration of order must be a domestic matter. Most of all, we must devise a stable policy, just as much as the Mexicans themselves.

DISCUSSION

Simp Spelling

The Editor:

Sir—I have received a communication from the Secretary of the Institute, presenting arguments prepared by one of the members, W. H. Shockley, in favor of certain so-called reforms in spelling, and also presenting the brief and sane reply of the president and board of directors against such reforms. My ballot has been forwarded, voting against the proposals.

Mr. Shockley and the spelling reformers mean well. Their avowed object is to "make our spelling conform better to the pronunciation"; meaning, one must assume, to the present pronunciation of our words. In this attempt they are committing a fundamental mistake, for pronunciation would prove an unstable foundation should it be made the basis of a reform in the spelling of our language.

(1) Pronunciation is not uniform. At the present time, words are not pronounced alike in different parts of the United States, nor in different counties of Great Britain (to say nothing of Ireland); not the same in Canada or in Australia. For example: 'Been' is pronounced *bean* in England, and *bin* in the United States. 'Can't', 'fast', 'last', 'half-past', 'worry', 'squirrel', are further illustrations.

(2) Pronunciation is unstable. As Mr. Shockley and the reformers state, the pronunciation of our words has changed in the past, and to my knowledge it is continuing to change at the present time. In New York for example, words, such as 'church', 'skirt', 'bird', 'hurt', 'Ernest', are usually pronounced *choich*, *boird* (*bowed* might be better), *sko-ect*, *ho-ect*, *Oce-nist*, by most New Yorkers. The usual pronunciation was formerly current in that city during my twenty years residence there. Contrast these with the sounds of the same words as pronounced in Scotland!

It is untrue to assert that "the spoken and not the written words constitute the language". Both constitute it, except among savage and ignorant races where writing and printing are unused. Latin, for example, is practically dead as a spoken language, except in the Catholic church; but it still exists in the form of innumerable books, documents, and inscriptions. The sounds of spoken words have an existence measurable in fractions of a second, and unless recorded (as by the phonograph), they cease to exist outside our memories. *Per contra*, written words have at least a visible and permanent existence.

Mr. Shockley rather praises our English language in

saying that it is the widest spoken of all. He advocates a "scientific spelling" to increase the spread of the language among foreign nations. It might accomplish that result; but the present limited spelling reform proposals are the reverse of scientific, proposing that we butcher only a score or so of words, as a beginning. Scientific reform of spelling would entail changes of a far-reaching and drastic character. For a scientific phonetic spelling we would first have to agree upon an accepted pronunciation for all our words—a difficulty indeed. The final result would be a language largely new; perhaps with forty letters in its alphabet. The vast collection of books in our public and family libraries would grow obsolete and unread excepting by those also educated in the present English language.

Even now attention is somewhat distracted when an American reads an average British publication, and the reverse; for the spelling reformers have already begun to confuse our common language. Let us beware of multiplied spelling creeping into further use under the alias of simplified spelling. If changes come, let them come by natural growth: the slower the better. The doubtful advantages offered by the small but noisy soviet of spelling reformers were well expressed to me a dozen years ago, by T. M. Hamilton, then superintendent of the Braden copper mine. He remarked: "I like this simplified spelling; you can spell any damn way you please."

Let us pray that our friends Shockley and Skeat will start to boom Esperanto, and let our language alone.

HAROLD ABBOT TITCOMB.

Farmington, Maine, January 5.

The Editor:

Sir—In the matter of 'simplified' (which I take to mean phonetic) spelling, it seems to me that there is an aspect more important than the mere change of orthography, and that is the effect such change would tend to have in crystallizing some special system of pronunciation; in short, the movement tends to reform not merely spelling but pronunciation. Not that a standardized pronunciation would be necessarily objectionable *per se*, but it does seem to me a grave objection that irresponsible individuals or societies should do the standardizing.

As an instance, take the word 'thot', which many (possibly including Mr. Shockley, I do not know) are trying to introduce in place of 'thought'. Now the sound almost universally attributed to the orthodox spelling, both in England and America, is 'thawt', which is not

the sound indicated by the spelling 'thot'; the latter word if pronounced strictly as written would be both provincial and cacophonous.

Another example of my contention may be taken from Mr. Shockley's own letter in your issue of January 10. He quotes with approval the word 'sulfid'; if this spelling is intended to be phonetic he evidently expects all of us to pronounce the word with a short 'i' in the last syllable, as in 'hid', but Webster's dictionary allows two pronunciations, and in my experience the one with the 'i' long, as in 'hide' is much more commonly used. Mr. Shockley may of course argue that 'sulphid' is more easily spoken than 'sulphide', though it is open to question whether the universal adoption of the former would not be a change for the worse, since the sound of the word 'sulphid' might easily be mistaken for 'sulphate'; but, in any case, the question is not of the desirability of a given pronunciation but of the right of 'simplified spellers' to dictate to us what intonations and vowel values we shall use in the spoken language.

Mr. Shockley's expression "amide the melting snows", which seems to have puzzled you, Sir, is I think an effort to throw derision on the accepted spelling of 'sulphide', which he appears to assume is, or ought to be, universally pronounced 'sulphid'.

Instances might be multiplied, but the two I have given are I think sufficient to show that the movement affects not only spelling but pronunciation also, and should be carefully watched.

E. M. HAMILTON.

San Francisco, January 16.

[No further letters on the subject will be accepted.—
EDITOR.]

A Stable Government for Mexico

The Editor:

Sir—Mr. Blamey Stevens' recent letter¹ and articles² are of suggestive and permanent value for those interested in Mexico. With most of his ideas and statements I am in hearty agreement, and it is in a spirit of co-operation rather than of criticism that I offer the following addition to his remarks:

Mr. Stevens has made a good beginning in attacking the problem by the scientific method of facing the facts, whatever they may imply, and had our American statesmen of recent years done the same, Mexico would not now be in its present dreadful condition. A country's political institutions reflect the character of its population, which in the case of Mexico may be roughly divided into three classes: the whites, 10%; the Indians, 40%; and the *mestizos*—half-breeds sprung usually from Spanish fathers and Indian mothers—50%.

The whites born in Mexico are locally called *creoles*, and are preponderantly of Spanish descent. None but

Spaniards were allowed as immigrants during the Colonial period; and, since its close in 1810, English, French, Italian, German, and American residents of the country have been greater in influence than in numbers, as they have belonged almost entirely to the educated middle class. One can readily comprehend the political attributes of the Spanish *creoles* only after a careful perusal of the history of the Colonial period.³ No European born in Mexico was ever allowed to hold any office under the viceroy, whose bureaucracy was always imported direct from Spain. Thus the *creoles* had no chance to acquire any political training until they managed finally to overthrow the Spanish power in 1821. During the past century, the *creoles* more or less dominated the government since their superior education and intellectual inheritance more than offset their paucity in numbers. Yet starting with the medieval political theories and practices of the Spanish autocracy of the XVIII century, the *creole* politicians have hardly advanced at all since that time, and for two reasons: first, because of the perennial revolutions, due to the ignorance of the masses; and second, because of their own character, entirely lacking in the usual initiative and enterprise of Western Europeans. This lack may be scientifically explained by the theories of inheritance⁴ for during three centuries, from Ferdinand and Isabella to Napoleon's invasion, the Spanish Inquisition extirpated by dungeon, faggot, or exile every individual of nonconformist social and political tendencies born within the Spanish dominions.

Consider next the class of Indians of whom Mr. Stevens says: "That the Indians are capable of high standards of civilization under a monarchy is well proved by their history," and "When Cortez arrived in Mexico in the XVI century, he found the Aztecs had a stable government and that civilization had therefore made great progress among them." In these sentences, Mr. Stevens falls into the same error—also recently promulgated by no less a personage than John Lind⁵—as does W. H. Prescott in his romantic history⁶, when he calls the Aztecs "civilized". Modern archeology, anthropology, and ethnology have completely discredited the fanciful parallels drawn by the Spanish chroniclers of the Conquest between the political institutions of the Aztecs and those of medieval Spain. If we divide human progress into three epochs: Savagery, Barbarism, and Civilization, and subdivide each epoch into three stages: Lower, Middle, and Upper, the Aztecs must be located in the Middle stage of Barbarism according to D. H. Morgan,⁷ who spent a lifetime in the study of the American aborigines. As Cortez' compatriots had reached the Lower stage of Civilization—implying a phonetic alphabet and the knowledge of steel tools—they were thus several milleniums of culture in advance of their Mexican subjects, who were certainly

below the Homeric Greeks and perhaps below the Egyptians of the First dynasty of nearly 5000 B.C.*

As our own Iroquois Indians had reached the culmination of the Lower stage of Barbarism in the XVI century, their institutions should be paralleled with those of the Aztecs rather than any in Europe. The Aztec 'monarch' thus appears merely the supreme chief of a confederation, his "nobility" rank as sub-chiefs of the various fighting clans, and his "law courts" are only inter-tribal councils of old men and braves. Like all barbarians in the Middle stage or below, the Aztecs were organized on the basis of population instead of territory, as the national and individual ownership of rigidly fixed tracts of land does not appear till the next stage of culture. The Indian tribal organizations had indeed confederated into an Aztec "nation", but the latter was still so incoherent as to fall to pieces before the first attack of a few hundred European freebooters captained by Hernando Cortez. Steeped in the cannibalism, the human sacrifice, and the religious fanaticism peculiar to Barbarian culture, the Aztec national organization, in its first feeble beginnings at the Conquest, was dissolved by the invasion into its original tribal elements, and has never since been able to make a fresh start†.

Contrary to the popular impression, the Mexican Indians were not all reduced to slavery by the Conquerors. A large fraction were protected from further creole molestation by the Law of *Egidos*, decreed in 1573 by Philip II, which set aside hundreds of reservations (*egidos*) in all parts of Mexico for the perpetual and exclusive use of the Indian villagers who occupied them. Each *egido* comprised a small central *sitio* (townsite) for the dwellings, and this nominally had an area of one square league around it, but as the boundaries were merely fixed by natural landmarks the actual area was often much greater. Though the *egidos* were located on hilly, wooded, or semi-arid lands—as the best tracts of valley lands had already been appropriated by the Spanish colonists—they enabled the Indian villagers to gain the rude living to which they were accustomed, independent of creole oppression. On the *egidos* the Indians preserved most of their ancient tribal customs and government, merely altering their Aztec bloodthirsty cult to a mild but superstitious form of Catholicism. They apportioned their communal lands for cultivation, and protected life and property within the village under the leadership of elected *caciques* or 'judges' as of yore. They had little to do with any Europeans, beyond perhaps some wandering friar, who might conduct for awhile a church and school, and the traders in the nearest creole town. They still spoke their Indian dialects among themselves, and even now there are millions of villagers who know little or nothing of the Spanish language.

Quite different was the fate of the Indians who were unlucky enough to be enslaved by the creole colonists. Treated like domestic animals, except for a perfunctory

instruction in Catholic rites, they soon lost their former tribal morality; and little or no restriction being placed on the consumption of *pulque* (maguey beer) and alcohol, acquired the vices, without the virtues, of their masters. There is now probably no more degraded working class in the world than these millions of Indian peons, either on the great estates, or in the mining and industrial cities whence thousands have migrated since the building of railroads in the 'eighties. Usually liars, thieves, and drunkards, they can only be compared morally with our semi-criminal class or the lowest type of Southern plantation negro.†‡ Often a newly-arrived American *entrepreneur* has tried to treat these peons as he would his own countrymen, but he has always been shamelessly deceived and plundered as a consequence. Every Mexican factory or mine, where there is anything worth stealing, must maintain a watchman at the gate, to search every peon leaving the establishment after his day's work, or soon all movable chattels will have disappeared. It is only fair to the Spanish colonists, however, to state that this criminality of the peon is only partly their fault, for the latter's Indian ancestors deemed morality a tribal matter, and like most barbarians did not consider it a crime to deceive or rob strangers.

Outside of the *egido* villagers, most Indian peons have some white blood and are thus properly classed as *mestizos*; these comprise the bulk of the middle and upper classes. In Brazil there is much negro blood among the half-breeds, but the Mexican *mestizo* is practically a pure white-red mixture and partakes of the characteristics of both sides of his ancestry. More intellectual than the full-blood Indian, the *mestizo* reflects the idea and habits of his family's social class rather than those of either ancestral race.

During the Colonial period and outside of the *egidos*, Mexico was organized economically on the Spanish feudal basis. The agricultural land was divided into great estates owned by the descendants of Spanish colonists or by the religious orders, while the masses were serfs. Between the landlords and the serfs existed a small middle class who were merchants, officials, teachers, priests, and the like. In the mining industry were three similar classes, though here the vagaries of mineral deposition made the hereditary class lines much less rigid than in agriculture.

The coming of independence altered scarcely at all the economic organization of society. The chief difference was in the office-holders, who were now creoles or *mestizos* instead of Spaniards. The departure of the Spanish troops and the partial arming of the masses during the ten-year struggle for independence had augmented tremendously the bands of brigands, which even in quiet Colonial times had never been entirely suppressed by the viceroys. Mining sank forthwith into a half century of desuetude, and there ensued a continuous series of revolutions, which lasted till the 'eighties. By the Reform laws of 1857, the church lands were con-

fiscated by the national government, under General Comonfort and Benito Juárez, yet as they were sold for a song and usually fell undivided into the hands of rich merchants, many of them English or French, the change of ownership did nothing to disturb feudalism but merely transferred a third of all landed property from religious to secular control.

Porfirio Díaz, a Oaxaca Indian partly educated for the priesthood, had become a general of the Liberal party during the French intervention, yet was so unprincipled as to rebel against President Juárez in 1871 and against President Lerdo de Tejada in 1876. Successful in his second attempt at supreme power, he managed to retain it, by hook or crook, until the Madero revolution ejected him in 1911. Though always professing liberalism, as president he soon fell under the political control of the great landlords, and during his reign did nothing directly to disturb their system of peonage for debt, which had been prohibited by the Constitution of 1857, or their ever-growing monopoly of the national resources. To offset these shortcomings, Díaz had two great political virtues—a firm desire to enforce internal peace, and a cordial hospitality to foreign industrial enterprises. Through the latter policy he was able to achieve the former, which had baffled his predecessors; for with the network of railways, built by Americans during the 'eighties, he managed so to multiply the effectiveness of the Federal army and the State rural police that brigandage ceased to be either safe or profitable as an occupation.

Though Díaz accomplished little, except in the few large cities, to reduce the illiteracy of the peons—owing to lack of funds and the opposition of both landlords and clergy to education—his welcome to foreign business created a powerful haven for their enlightenment. By working for an American mine or railway, the peon not only enjoyed higher wages than under his feudal masters but felt, for the first time, the stimulating and broadening effect of the free labor system. From his association with foreign foremen and artisans, he acquired, along with technical skill, an acquaintance with both political democracy and trade-unionism—a knowledge which had hitherto been confined in Mexico to the intellectuals. Moreover, under Díaz, there was a large relative increase of the middle class, for the free schools in the cities, although too few to lessen appreciably national illiteracy, were yet sufficient to endow many peon children with enough learning to qualify as clerks or petty officials.

As offsets to these benefits of the Díaz regime were some serious factors tending to social unrest. The bulk of the peons, still illegally chained for debt by the landlords as of yore, were becoming impatient of duress and longed to escape and to work as free laborers for the foreign enterprises, as so many of their relatives and friends had already done. Secondly, the *haciendas* (great estates) had become a serious impediment to further economic progress. In 1910 some 11,000 families owned 880,000 sq. km. of land or 44% of the national territory, and this property included the bulk of the best arable soil.¹¹ Through its control over Díaz, the landlord party

almost exempted the *haciendas* from taxation, by false assessments, and threw the growing burden of government either upon the foreign mining and industrial enterprises or upon the native masses. Most landlords held much of their good land idle, either for speculation or because too lazy to develop it; as a consequence the country was unable to feed itself a good part of the time and was saved from famine only by extensive importations of maize. The maguery-growing landlords, also, were responsible for the besotting of the peons of all the cities of the Central Plateau by *pulque* and alcohol, for they opposed any such restriction of the liquor traffic as is practised by other civilized governments.

Thirdly, the growing middle class with their half-baked knowledge began to be insanely jealous of their foreign rivals for employment with the numerous alien corporations, fancying that the preference enjoyed by the latter in place and pay was due to race favoritism and national prejudice rather than to superior ability and integrity. Many carried their envy so far as to become active partisans of the anti-foreign faction, which frankly proposed not only to prohibit further immigration but to expel all foreigners from the country, confiscate their property, and turn Mexico into a closed preserve for the *mexico* race.

Last, but not least, of social disturbers were the predatory elements in the foreign business invasion. The law of 1857, nationalizing church property, had also authorized the abolition of the *ejidos*; but this unwise measure produced no marked bad effects till the advent of railways, in the 'eighties, made the Indian lands attractive to foreign speculators. Then, by conspiracy with corrupt native officials, these latter obtained from the Mexican Congress the *Deslinde* laws¹² of 1883 and 1894 which, under the guise of re-surveys and colonization, enabled the conspirators to obtain title to a large part of hundreds of *ejidos* and evict their Indian owners. In this way, myriads of Indian villagers were deprived of their ancient communal lands and obliged to wander forth in search of employment as penniless peons. Meanwhile a few dozen land companies had gobbled up 10% of the whole country.

Such, in brief, was the condition of Mexico in her gay Centennial year of 1910, when Díaz finished his seventh presidential term after 34 years of power. In spite of the seething unrest, the coming revolution might even then have been avoided had the dictator been wise enough to retire in favor of some enlightened and progressive successor. But the aged autocrat yielded to the pleas of the corrupt ring of grafters—called popularly *científicos*—under whose tutelage he had been for many years, and he not only had himself "re-elected", but also named as vice-president, and probable successor, the corrupt reactionary Ramon Corral. This error gave Francisco Madero his opportunity and, defying the feeble old

¹¹'El Latifundismo Mexicano', by R. B. Brinsmade, Libreria Bonret, Mexico City.

¹²'Leyes sobre Tierras de 1863 a 1912', Dept. of Fomento, Mexico City.

lion of Chapultepec, he raised the standard of revolt in the north and soon had the nation at his feet.

Successful as a revolutionary apostle, Madero entirely lacked the executive talent and constructive ability required at that time by the presidential office. Instead of correcting the crying economic wrongs of illegal peonage, unfair taxation, and the despoiled *giles*, he busied himself with "effective suffrage", an article which the average Mexican knew little about and cared even less. By 1913, when overthrown by the Huerta military conspiracy, Madero had lost his popularity and it was only by becoming a heroic martyr that his name was again enshrined in the hearts of the masses.¹³ The Centennial year was the end of the quarter-century of Porfirian peace, for brigandage then began to revive with the break-up of the rural police system and the encouragement given by the Madero party to every armed adherent, whatever his moral character or practice.

The problem of perennial brigandage is usually explained by considering the Mexican from the standpoint of the 'economic man' of the textbooks. Oppressed by his masters and having nothing to lose except his life, the peon takes to brigandage as a business proposition, where a lucky encounter may make his fortune. This sounds plausible, but in only a minority of the actual cases does it probably accord with the facts. While the bulk of the Indians were immobile agriculturists, and had thus outgrown the hunting stage of culture, on the advent of Europeans in 1521 there yet remained many backward tribes and numerous atavistic members of the advanced tribes who were still natural rovers. And such is still the condition after four centuries of Spanish domination. Scratch a bandit or 'revolutionist' and you often find, not a designing criminal, but a savage who prefers the wild life of the woods and hills, with all its uncertainties and hardships, to anything that can be offered of comfort or well-being within the necessary restrictions of civilized discipline. While the brigand for economic reasons may evidently be eliminated by abolishing class privileges and making honest industry more profitable than theft, the bandit of atavistic inheritance can only be suppressed by an adequate police force, and this simple fact, acted on by Diaz, has been disregarded by our Democratic doctrinaires in their writings about Mexico.

It is unnecessary to review here the disgraceful events that followed the triumph of the 'Constitutional' party in 1914 and the flight of the reactionary Huerta, as they have already been detailed in the 'Press' by its various correspondents, especially during 1916.¹⁴ Suffice it to say now that the victors split at once into several contending factions and after a series of bloody battles in the spring of 1915 around Celaya, the Carranzistas overcame their chief opponents, the Villistas, and have ever since dominated the chief cities and their connecting railways. Instead of restoring the Constitution of 1857, for which they had ostensibly fought Huerta, the Carranz-

istas, after their enemy's flight to Europe, proceeded to suspend the Constitution for an indefinite period. This 'Pre-Constitutional' interim lasted from September 1914 till the inauguration of the new or Carranzista 'constitution' in May 1917, which was a document entirely unconnected with the former constitution and therefore by its criterion quite unconstitutional. However, this lawless interim served its projected purpose well, for it effectually shielded from any future legal reckoning the countless crimes committed by most of the Carranzista leaders between 1914 and 1917. Among these crimes, the repudiation of P1,250,000,000 paper money in 1916, and the looting of the banks of issue shortly after, were only nation-wide examples of the shameless greed and chicanery that devastated every locality visited by the self-styled reformers, who, like a flight of human locusts, caused the deaths of myriads of Mexicans from famine and hunger-typhus.

Were Mexico a hermit empire, like the Japan of 1850, her present political and economic condition, however distressing for her people, might be of intense interest to historians but to few other foreigners. Unfortunately for the outside world, Mexico ceased to be a hermit State in 1821; and, by 1910, her policy of advertising for and welcoming the investment of foreign capital had resulted in her absorption of nearly two billion dollars of alien cash, of which over one-half came from the United States. Along with the capital had come a large number of high-grade immigrants to look after its management and make their homes in the country. The present revolution, which has now lasted for nine years, has destroyed or rendered unproductive from inaction the greater part of this foreign capital, and has compelled the repatriation of most of its foreign guardians and attachés for lack of means of livelihood.

The dictatorship of Diaz, however unsatisfactory from many standpoints, was at least friendly to foreigners and kept faith with its creditors, as is proved by its high standing in the international money market. After nine years of disorder, urban Mexico now finds herself under the dictatorship of Carranza, which is unfriendly to foreigners and has no international credit at all. Yet the Carranzista policy is probably more representative of Mexico than was that of Diaz, for the majority of literate Mexicans—the only kind that counts politically—are jealous of foreigners and so dishonest in commercial transactions that most large business operations, which require credit, are necessarily conducted by aliens.

Practically, if not nominally,¹⁵ an international outlaw, Mexico can only resume her former position as a decent member of the family of nations by accomplishing three things: first, the suppression of the brigandage which now renders unsafe, in most parts of rural Mexico, the operation of foreign mines, railways, plantations, and factories; second, the payment of the coupons of the bonds of the national debt and railways, in default since

¹³ 'Political Shame of Mexico', by Bell.

¹⁴ 'M. & S. P.', Vol. 112, pp. 175, 525, 873; Vol. 113, pp. 88, 155, 605, 874.

¹⁵ The Carranza government has been recognized by the United States as 'de jure', but not by England, France, or the League of Nations.

1913; third, the satisfaction of all claims by foreigners, for loss of life or property during the present revolution, which are recognized as legitimate by international law. That the Carranza government is capable or even desirous of achieving these objects is much less probable than the birth of white elephants in Siam, if anything can be predicated from its record during five years of power. And even less can be hoped from its rivals, the Villistas, the Felicistas, the Oaxaqueños, and the Zapatistas, even though the latter factions succeeded recently in hoodwinking the adventurous Mr. Gates.¹⁷

Being thus forced by the outstanding facts to adopt Mr. Stevens' conclusions that foreign intervention is necessary if Mexico is to be pacified and restored to international decency, we can next proceed to examine his practical proposals for its accomplishment. In his first article, he suggests methods for an intervention by the League of Nations, and in his second, he demonstrates clearly from history, a subject too often ignored by radical doctrinaires, that a democratic form of government will only suit a nation that has become sufficiently developed politically to understand and operate it. As a large majority of the Mexican people is still living in the Barbarian stage of culture, it is highly misleading to compare its "revolutions" with those of modern France, as superficial native and even foreign writers are fond of doing, for those of Hayti¹⁸ are much closer in kind. A foreign intervention will not therefore be a peaceful relief expedition, as Mr. Stevens seems to imply, but an armed invasion able and willing to overcome the resistance that must be expected from the native faction in power at the time.

During the intervention, no aid should be requested from any of the factional chiefs, whether civil or military, for nearly all are hypocritical and untrustworthy. When Mr. Stevens remarks: "Among Mexicans who can read and write, the average standard of education and culture is probably higher than that obtaining in the United States," he may be correct in that the book knowledge of the 10% of literate Mexicans exceeds the average acquirements of the 90% of literate Americans. Nevertheless he gives a false impression, for the chief requirement for his proposed Supreme Court to control elections would be moral character rather than book knowledge, and in this quality the Mexicans would stand far behind the Americans. If Mexico had possessed any such clan of patriotic, brave, and unselfish leaders as the Samurai of Japan, she would long ago have attained to a stable civilized government in spite of her barbarous masses. While a few score men may be found among the 12 millions of Mexicans who measure up to the moral code of the Samurai in their individual practice, they are passively rather than actively virtuous, and, lacking completely the faculty for organization, they are helpless to oppose the political schemes of the numerous and

cunning demagogues, backed as the latter are by hosts of armed brigands. It is safe to say that these chosen few can never make their uplifting influence felt in the Mexican government until supported by foreign troops.

While a foreign intervention should naturally be made in the interest of the millions of peaceful Mexicans—the innocent and otherwise hopeless victims of the brigand political factions—as well as for the enforcement of treaty obligations, it seems both useless and rash to precede it by the lengthy investigations and elaborate diplomatic and military preparations suggested by Mr. Stevens. The few high-minded natives, whose advice might be valuable, could not be reached by the investigators, for they are not in exile but are living in retirement in the interior; while the longer notice the brigand-factions have of the proposed invasion the worse it will be for both their local victims and the invading army. On this basis, the seven procedures of Mr. Stevens' plan can be easily condensed into the two following: First, after due notice of intention let the mandatory of the League of Nations blockade all Mexican ports and invade the country, from several points simultaneously, with an overwhelming force so as to minimize the bloodshed of capture; second, as soon as organized resistance ceases, form a civil government modeled after the first American structure in the Philippines, with its provisions for universal compulsory education, for a rural constabulary, and for the filling of all possible public offices with qualified natives.¹⁹

Both before and after the intervention, the mandatory nation should seek the co-operation of all patriotic intellectual Mexicans in explaining to the ignorant masses that no suppression of their nationality is either proposed or desired, but that the main object of the new government will be to protect them against further depredations of their own criminal elements until they can become sufficiently educated to know how to protect themselves. How long this educational process must last before Mexico can be safely released from tutelage can only be surmised, but judging from our similar experience in the Philippines—whose population²⁰ is close to the cultural status of the Mexican—it may require a generation or more.²¹ However that may be, I must disagree with Mr. Stevens when he says, "Education must be along the best ideals of Mexican national life and not the ready-made system of the United States or any other country." Does Mr. Stevens here refer to the ideals of the Aztec barbarians or to those of the Spanish exploiters of the Colonial period, for these are certainly the only ones poor Mexico has by national inheritance? To achieve its object must not the new educational system be based on an entirely different set of ideals from either of these?

Elements of Smelting-Plant Design—I

By OLIVER E. JAGER

INTRODUCTION. This article is intended for younger members of the profession, and is an attempt to explain the method of selecting some of the appliances usually found on a modern smelter, as well as to discuss pertinent generalities. A book could be written on smelter-design, and it is reasonable to suppose that some engineer who has specialized in this particular branch—such as, for example, A. G. McGregor—will eventually make this much-needed addition to technical literature. In an article of this nature the treatment of the subject will necessarily be sketchy, as many of the problems are presented as they have occurred in practice, some being answers to questions asked by young engineers when starting work at a smelter. Only the metallurgical side of the subject will be treated, with brief reference to cognate subjects.

In considering equipment in general, it is well to remember that, with a few notable exceptions—such as, for example, the Dwight-Lloyd sintering machine and the Cottrell dust-precipitation apparatus—the principal appliances in a copper or lead smelter have been borrowed and adapted from the metallurgy of iron. For this reason, it is my opinion that a visit to a steel-plant is always worth while, as it is seldom that one comes away without having picked up some detail about machinery or method to repay the trouble of the visit. One noticeable feature—worthy of emulation—is that everything about a steel-plant is doing work and getting results. Whether the steel-men (like the medical profession) bury their mistakes, I do not know, but it is a fact that, on a steel-plant, one seldom sees any of those monumental junk-piles or rusted and un-used aggregations of machinery that are often noticed at a copper or lead smelter, especially in isolated localities, where one would think standard equipment would be used, and not the new patent process invented by a retired grocer, or the wondrous machine conceived in the brain of some clever inventor who never worked a smelting-furnace.

SIZE OF PLANT. Let us now take an imaginary case of a copper smelter with a daily capacity of 1000 tons of ore, to serve as a framework on which to hang these notes. The first question that may be asked is why this particular capacity was selected by the designers. To answer this one must go to the financial side of the case, and it may be as well to emphasize here that, in the last analysis, metallurgy is a matter of dollars and cents. The primary object of every manufacturing process is to make money. If a smelting-works (which is really a factory) produces bullion with a market-value of \$200 per ton, but which costs \$220 per ton to produce, it is only a question of time until the concern goes bankrupt. It makes no difference how pretty a process may be

chemically, or how skilfully it be applied, if the resulting product cannot be disposed of at a profit, the process is a failure. This sounds like a truism, but it is surprising how often it is disregarded.

Assuming that the smelter is to treat the entire daily production of the mine, the size of the plant is thus regulated. This production, however, must be at a rate such as to pay interest on the capital invested and provide amortization for the plant. If the production is too low, no profit at all will be made. While increased output does not mean a proportionately increased operating expense, since fixed charges remain more or less constant, it is possible to have production too high; that is to say, there will be so great an expenditure on plant to handle the large tonnage, that any saving on fixed charges becomes doubtful, or may even become negative and result in a loss.¹ A certain relation between ore-reserves and treatment-capacity must be observed, hence the plant should not be too large for the amount of ore developed, as a plant not operated to capacity is not being operated economically. When machines and appliances are lying idle they are returning no interest on the money invested in them. It would seem almost unnecessary to add that a treatment-plant should not be erected until a sufficient tonnage of ore has been actually developed to warrant the investment, were it not for the fact that the neglect of this precaution has been the cause of much loss in the mining business. In other words, there must not be a smelter before there is a mine.

Regarding the amount of capital invested, it is well to remember that this must be sufficient not only for the necessary purchase of property and equipment, but also to provide enough money to carry on operations until the product is on the market, as it is only then that returns will commence. This question of the time that elapses between the mining of the ore and the marketing of the final product is a very important one. That it is frequently overlooked is also true. For the enterprise to be successful, whatever capital is invested must be repaid, with interest, before the business is wound up, which brings us to the consideration of amortization.

Amortization is the redemption of capital by annual payments to a fund set aside for the purpose. This fund is independent of dividends and is arranged to repay the original investment at the end of a certain period of years. The fund is put out at compound interest, or invested in some form of easily-realizable security, so that the total to be set aside will be less than the amount invested.² A plant may be regarded as a tool for perform-

¹H. C. Hoover. 'Principles of Mining'; chap. 15.

²Hoover, op. cit., chap. 5; also Finlay, 'Cost of Mining'; chap. 3.

ing certain work. When the work is completed, the tool may or may not be serviceable for other work; it is safer to assume that it will not. A smelting-works is a collection of appliances for treating ore. When the ore is all treated, that is, when the mine is exhausted, the purpose for which the plant was erected has been attained, and it may then be regarded as a collection of second-hand machinery, a great deal of which could neither be realized upon nor removed. In practice this state of affairs rarely obtains, as a progressive company with a good plant is on the look-out for new supplies of ore long before the original mine has become depleted. In any case the cost of the plant must be defrayed out of the profit made by it; hence the application of amortization to it. This re-payment is often called 'depreciation', especially by writers on accounting, who will 'amortize' a bond-issue, but 'depreciate' a plant.³ This apparent confusion of terms is probably due to the fact that the usual meaning of the verb 'depreciate' is 'to become of less value'. If a new plant is worth \$1,000,000, it may be assumed to be worth, say, \$900,000 at the end of a year; that is, it has 'depreciated' in value. While this is true enough, any sum written off for the re-payment of the cost of the plant is really an amortization charge, though one frequently finds depreciation used in this sense. Finlay⁴ regards depreciation as nothing more than maintenance, or current construction and improvements. Whatever nomenclature is adopted, charges for maintenance of the plant and for the re-payment of its cost should be included as part of the operating expense.

In the preliminary estimation of operating cost, a charge must be made for amortization, as it may be found that, on account of this charge, it would be more profitable to send the ore to a custom smelter than to erect a new plant to treat it. The rate of amortization usually adopted in preliminary estimates is 10%. This does not mean that the business will be wound up in 10 years, nor that the plant will be worn out in that time, though furnaces and other appliances subject to hard usage are not good for much more. It must be borne in mind also that improvements in metallurgy are constantly being introduced, so that a plant that is modern today may be out of date ten years hence. The preliminary calculation for the amortization charge per ton is made as follows: Suppose a plant of 365,000 tons annual capacity cost \$1,825,000 and that it will have a life of 10 years; then $\frac{1,825,000}{10 \div 365,000} = 50$ cents per ton of ore treated. This is the same as saying that if a plant cost \$5 per ton of annual capacity, the amortization charge per ton treated will be 10% of this sum. To obtain accurate cost-data on operation, this 50c. should be distributed among the various departments—blast-furnaces, converters, reverberatories, etc.—on the basis of tonnage of ore or matte treated, with due consideration of the probable life of each group of appliances.⁵

To sum up: Money must flow into the treasury at a

certain rate. As this money comes from the sale of copper and contained precious metals (if any), a certain tonnage of product must be shipped each month from the smelter. While the mine output, and hence the capacity of the plant, are thus theoretically determined, in practice there is always a certain amount of leeway, since allowance must be made for various contingencies, such as variation in metal-prices, change in grade or character of ore, necessary repairs to furnaces, etc. For this reason a small proportion of extra plant is generally provided. That is to say, to ensure the continuous treatment of 1000 tons per day, the plant should be capable of treating in the neighborhood of 1150 tons. This does not conflict with what was said previously about idle plant, as the maintenance of a steady output will more than offset the loss of interest, provided, of course, that the number of extra units be not excessive. Finally, emphasis must be laid on the fact that it is impossible to extract 100% of the metal-values of an ore. Proper allowance must be made for this when figuring the tonnage of ore necessary to yield the required output.

LOCAL CONDITIONS. In the first place, these are of importance in deciding where the plant shall be situated. Since the mine is a fixture, it must be determined whether it is better to place the smelter near the mine, or to erect it at some more or less distant point and haul the ore to it. This would mean a consideration of the railroad facilities already existing, or of the construction and operation of a new line of railway. An alternative would be to employ motor-traction and allow for the maintenance of roads. The question of getting fuel and supplies to the smelter must also be considered; so that, so far as transportation is concerned, the matter resolves itself into the selection of a scheme involving the fewest total ton-miles, or, more correctly, the least amount to be paid out in freight, taking into consideration all incoming and outgoing material. Unfortunately, transportation is not the only factor in the case, as the questions of water-supply, proximity to farm-land, and suitable site for the smelter often take precedence. With the development of the Cottrell process, the business of 'smoke-farming' is not nearly so lucrative as formerly, although the question of smoke may have a bearing on the case if the expenditure for a fume-precipitation plant is not desirable. An adequate water-supply is of prime importance, although this must not be taken to mean that water-recovery schemes are not efficacious. Many plants are able to operate solely because of a well-designed equipment enabling them to use the same water (or a good proportion of it) over and over again. Regarding the plant-site itself, nothing need be said here, as the various advantages and disadvantages of hill-side, sloping, and level sites, as well as the consideration of the nature of the ground for supporting buildings, have all been treated in text-books.

In passing, it may be mentioned that there are two items to which sufficient attention is not always given: Provision for future enlargement of the plant, and suitable facility for the disposal of slag. The question of

³R. H. Montgomery. 'Auditing—Theory and Practice.'

⁴Loc. cit.

⁵Herbert Haas. 'E. & M. J.'; Feb. 19, 1910.

power often has considerable influence on the choice of a site, as proximity to a source of cheap power is a desideratum of no mean importance. Labor is another factor that must be considered, both as to quality and quantity available at the existing wage-scale in the district. The geographical position of a plant often affects the supply of labor, as men have a tendency to gravitate toward towns and to avoid isolated localities. To hold men in outlying settlements, considerable attention must be given to housing, food, and opportunities for recreation. In foreign countries, local politics may enter into the matter, as well as the question of the distance from

charge under reducing conditions. Accurate data on sintering can be obtained by making tests in a pot of about 10 in. diameter, provided with a grate to support a few pounds of the ore or mixture under examination. A tight-fitting top is clamped on the pot, and a light blast of air introduced above the charge, which is ignited with straw or shavings. The results so obtained can be reproduced closely on the sintering machine. There would be little use, however, in fusing a heavy sulphide ore in the muffle, as the oxidizing conditions of the pyritic or semi-pyritic blast-furnace would be absent. Sizing-tests, with assays, are useful in showing whether

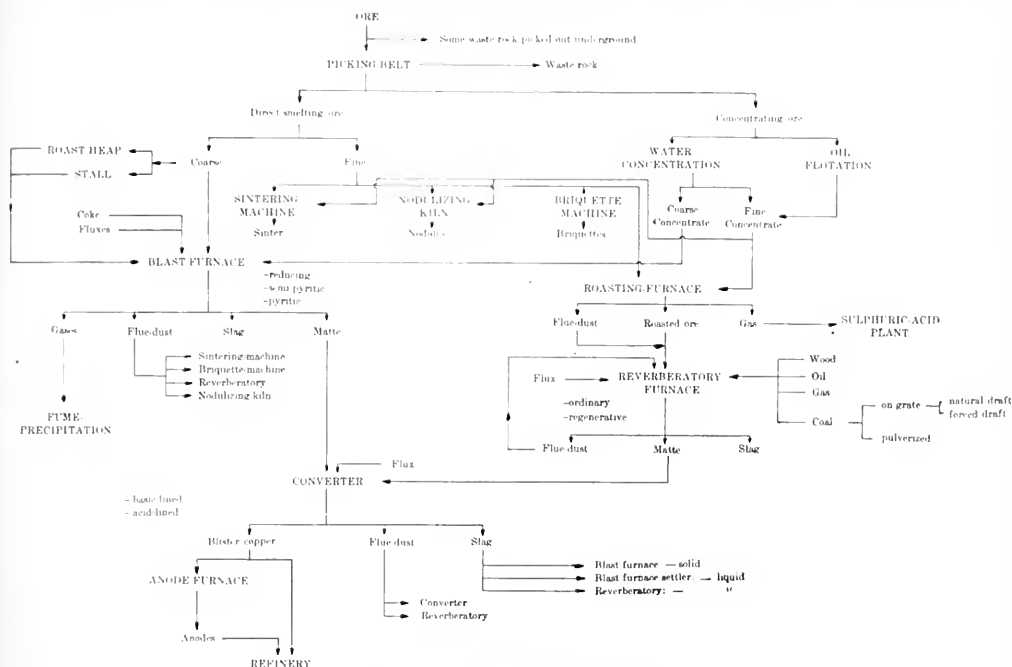

TABLE I. PROCESS OF TREATMENT

the market where the product is sold, and where fuel and supplies may be purchased. In general, local conditions may be divided into two classes: Those pertaining to technical matters, and those into which the human element enters.

SELECTION OF THE PROCESS. This is a wide question and has been taken up in various text-books.⁶ It is true, it does not always receive proper consideration by those contemplating the erection of a plant. Actual furnace tests of an ore are not often made, and if made on a small scale, the results are apt to be misleading unless carefully interpreted. Laboratory tests are of value if they correspond to large-scale operations, as, for example, in the case of an oxidizing roast. To mention other cases: By means of fusions in charcoal-covered crucibles in a muffle with a reducing atmosphere, considerable information may be obtained about the behavior of a blast-furnace

charge under reducing conditions. Accurate data on sintering can be obtained by making tests in a pot of about 10 in. diameter, provided with a grate to support a few pounds of the ore or mixture under examination.

A tight-fitting top is clamped on the pot, and a light blast of air introduced above the charge, which is ignited with straw or shavings. The results so obtained can be reproduced closely on the sintering machine. There would be little use, however, in fusing a heavy sulphide ore in the muffle, as the oxidizing conditions of the pyritic or semi-pyritic blast-furnace would be absent. Sizing-tests, with assays, are useful in showing whether the metals occur in the coarse or in the fine portion of the ore.

⁶Peters, 'Modern Copper Smelting'; Barr, 'Testing for Metallurgical Processes'.

vey publications and maps, bulletins of the Bureau of Mines, and the technical press in general, are the usual sources of information.

The nature of the ore must be fully determined, so that it can be stated that it is, let us say, a mixture of various sulphides in a certain gangue. The problem may not be so simple, as it may be found that the mine contains two or more different classes of ore which must be regarded as separate constituents of a furnace-charge, or which will require separate schemes of treatment. Complete analyses of samples from the several orebodies would, of course, be made, and these should be supplemented by a mineralogical analysis for determining the proportion of each mineral present in the ore. Among other things, this is useful in showing how the ore would concentrate, and how the various metals occur in it. The method of doing this has already been published by Larison,⁷ and Sale illustrates the use to which the information is put.⁸ Should such an examination not be possible, the proportion of each mineral present may be calculated approximately from the complete analysis of the ore, providing the various minerals and the gangue have been identified. In most cases it would be sufficient to divide the ore under examination into useful minerals and gangue, as will now be illustrated by applying the method to the Sudbury nickel ore. These notable ore deposits have been fully investigated, so that there is plenty of available information about the minerals present, the mode of occurrence of the copper and nickel, and the nature of the gangue.⁹ Briefly, the ore is a mixture of chalcopyrite and pyrrhotite in a norite gangue, the nickel being present as pentlandite associated with the pyrrhotite. While the composition of the ore varies at different mines, the following analysis will serve the present purpose.

	%		%
Ni	2.3	SiO ₂	26.8
Cu	1.9	CaO	3.4
Fe	29.1	MgO	4.2
S	17.2		
Al ₂ O ₃	9.0		33.9
		K, Na, O (not determined)	6.1

Calculation of sulphides present: Pentlandite is of too uncertain a composition to be represented exactly by the formula (FeNi)₉S₈, but an average analysis compiled from Coleman's figures gives; Ni, 35.6%; Fe, 30.6%; S, 33.8%.

Chalcopyrite, CuFeS₂ = 64 + 56 + 64 = 184

Pyrrhotite, FeS₈ = 448 + 288 = 736

Applying these figures to the analysis we get:

	Sulphide	Fe %	S %
2.3% Ni represents $\frac{2.3}{35.6\%}$	or 6.46% pentlandite containing 1.98	2.18	
1.9% Cu " $\frac{1.9 \times 184}{64}$	or 5.40% chalcopyrite "	1.66	1.90
	33.53% pyrrhotite "	20.41	13.12
		24.05	17.20

There being no other sulphides present, all the sulphur (17.2%) must be accounted for here; therefore 17.2 - (2.18 + 1.9) or 13.12 = sulphur in pyrrhotite, from

⁷E. L. Larison, 'E. & M. J.', May 2, 1914.

⁹A. P. Coleman, Bull. 170, Dept. of Mines, Canada; Report of the Royal Ontario Nickel Commission, 1917.

which the corresponding iron and the amount of mineral are calculated.

The sulphides amount to 45.45% of the ore, therefore there is 54.55% of gangue. The gangue consists of various silicates composing the minerals of the rock norite, a basic rock containing plagioclase feldspar and pyroxene. Kemp defines it as gabbro with hypersthene instead of augite.¹⁰ From the formulas of these minerals we find that, metallurgically speaking, they are mostly bi-silicates and mono-silicates. The following table shows the combination of the elements in the gangue according to their silicate-degrees.

Original	Percentage			
SiO ₂ ...	% of gangue		Base	Silica Silicate
Fe ...	26.8	49.12		
Al ₂ O ₃ ...	9.0	16.50	(11.90 FeO)FeO SiO ₂	11.90 + 9.92 = 21.82
CaO ...	3.4	6.23	2Al ₂ O ₃ .3SiO ₂	16.50 + 14.56 = 31.06
MgO ...	4.2	7.70	2MgO.SiO ₂	6.23 + 3.34 = 9.57
Na ₂ K ₂ O ...	6.1	11.19	MgO.SiO ₂	7.70 + 11.55 = 19.25
			2(NaK) ₂ O.3SiO ₂	8.55 + 9.87 = 18.42
	54.55	100.00		49.24 100.12

Explanations:

Fe in gangue = 29.1 - 24.05 = 5.05

O with Fe = 11.90 - 9.26 = 2.64

(NaK)₂O = 11.19 - 2.64 = 8.55

The alkali metals not being separately determined, we will assume them to be present in equal proportions, and give (NaK) an average combining-weight of 31.

From this mineralogical analysis we make the following deductions: 45.45% of the ore consists of heavy sulphides, and practically all the easily fusible material in the ore is contained in this portion. If this ore were subjected to an ordinary gravity concentration, the ratio of concentration would be but $\frac{100}{45.45}$, or 2.2:1 (assuming

100% recovery), and the concentrate would be a mass of sulphides high in iron. The analysis of the concentrate would be as follows: Fe, 52.9%; S, 37.8%; Ni, 5.1%; Cu, 4.2%. Nothing would be accomplished by such a procedure, as silica would have to be added again for fluxing. It would be highly advantageous, however, if some selective concentrating-method could be applied, so that the proportion of copper and nickel could be increased, and that of the diluting iron-sulphide diminished. There is no free silica present. Although the gangue contains 49.12% silica, it is not available as a flux, since the whole of it is already in the combined state, a condition frequently encountered in the Sudbury ore, though blebs of quartz are sometimes found scattered through it. This lack of free silica, together with the somewhat large amount of alumina, has been advanced as a reason for the failure to smelt the Sudbury ore pyritically. It may be mentioned in passing, however, that this ore has a certain amount of fluxing power when used in the converter, the explanation presumably being that the silicates are decomposed and a silicate of lower degree formed. A certain amount of iron oxide may also be dissolved in the fused silicate and thus carried out in the converter slag.

Returning to the general plan: the ore, or a portion of it, may or may not require concentration. Omitting this from consideration and confining our attention to

¹⁰Peele, 'Mining Engineer's Handbook'; p. 76.

fire metallurgy, we find that the method of treating a copper ore lies within somewhat narrow limits. The old division of the ore into coarse and fine, treating the former in the blast-furnace and the latter in the reverberatory, still holds good in the majority of cases. It is true that there are more modifications of this rule than formerly, principally owing to the development of the reverberatory furnace, as it may be found more profitable—again the money-question—to crush coarse ore and smelt everything in the reverberatory, than to maintain blast-furnaces to treat the coarse material. The reverse condition would be a plant containing blast-furnaces only, in which case the fine ore would have to be agglomerated by some process before smelting. Certain ores, of course, are better adapted to the blast-furnace than to the reverberatory.¹¹ An interesting example of the selection of blast-furnaces for a smelting works treating concentrate, with the reasons for doing so, is to be found in an article entitled 'Metallurgical Operations at the Braden Copper Co.', by R. E. Douglass and B. T. Colley.¹² This article shows not only how local conditions may affect the selection of appliances, but also illustrates how a process may suffer modifications as new conditions arise.

In every case the process must be so adapted to the ore that the greatest possible profit results. This requires the consideration of the cost of everything entering into the process, and the probable results that will be obtained from the use of it. The accompanying tabulation is intended to supplement the explanations found in textbooks, and, while admittedly capable of enlargement, gives an outline of the usual stages of treatment of a copper ore. It is not a flow-sheet, but is intended to show the various available methods of treatment, from which, by proper selection and combination, a suitable process may be worked out. Oxidized ores have not been included.

SMELTING THE ORE. The consideration of the results obtained by various methods of smelting being a prime necessity in selecting the process, it will be taken up under this heading, although it is really a part of the preceding section. To exemplify the fundamental principles, we will assume that (for some reason) a reverberatory plant is not feasible, so that a combination of blast-furnaces and sintering-machines has to be considered for smelting the ore. While what follows is used here for the purpose of illustration, it must be understood that, in actual practice, preliminary estimates of all possible methods and combinations, with the probable cost and the resulting production, are worked out for comparison. To do this successfully requires experience, judgment, and imagination, since the estimator must be able to form a mental picture of all the details of the process in order that no necessary step, machine, or man be omitted. An excellent example of this class of work is to be found in an article entitled 'Blast-Furnace v. Reverberatory', by B. Magnus.¹³

(To be continued)

Labor Unrest in South Africa

Direct testimony to the fact that 'labor unrest' is not confined to our own country or even to the white race, is contained in a review of the native labor situation by Col. C. W. Villiers, chairman of the Native Recruiting Corporation, Ltd., of South Africa, as reported in a recent issue of the 'South African Mining & Engineering Journal', of Johannesburg, from which the following is quoted.

There has been evidence during the year of a certain amount of unrest among the natives, both in the mines and among those in other employ, and this was on the point of developing when during the months of March and April serious trouble arose among natives employed on other than mine work in the various municipalities on the Witwatersrand. This trouble arose through a desire by natives for a general increase in wages, and was instigated by educated natives, who professed to be the leaders and representatives of the native workers. These self-appointed leaders of the natives had, since July 1918, been agitating for a general increase in native wages, and finding themselves unable to bring this about in any direct manner they advised all natives to return their passes to the Government offices, and to decline to take out fresh ones. On March 19, just prior to these agitations taking any concrete form, the Johannesburg branch of the Transvaal native congress wrote a letter to this corporation, requesting an interview on behalf of native workers for increased wages in the mines. Anticipating trouble, it was deemed advisable to send for representative native chiefs and headmen from various parts of British South Africa, for the purpose of preventing the spread of any influence the members of this native congress might bring to bear on the native workers at the mines.

A very representative gathering of native chiefs in Johannesburg was the result, and the presence of these real representatives of the natives no doubt went a long way toward preventing the disaffection spreading to the natives on the mines. The disaffection in the municipalities was accompanied by serious rioting, and many collisions with the police. The action of the corporation in sending for the native chiefs to come to Johannesburg was very strongly resented by the members of the Johannesburg branch of the Transvaal native congress. Mr. Taberer, the general manager, considered it advisable to endeavor to have a private meeting with the latter body, which he accordingly arranged, and held on April 29. Mr. Taberer was able to bring reason to bear on the members of the congress, some of whom, from their speeches, made it very clear that they were preparing for serious trouble, and from the date of the holding of the meeting the natives ceased to openly refuse to take out or carry passes. It is understood that full investigation is being made by the Government into the general question of the 'pass laws', with a view to the amelioration of any hardships under which the natives may be laboring.

The Mining Industry in Australia

By F. H. BATHURST

Early in the War there was given in this journal an outline of the manner in which certain groups in Australia were eliminated as the result of the attempt of Mr. Hughes, the present Prime Minister of the Commonwealth of Australia—then its Attorney-General in the Labor Ministry—to destroy the dominance that the houses of Merton of Frankfort, Beer Sondheim, Aron Hirsch, and other German metal merchants exercised over the metal trade of this country. At first the attitude of Mr. Hughes was resented by Australian mining men who had been associated in one way or another with these alien dealers, not because they wished to conserve alien interests, but because they were suspicious of the political motives underlying the vigorous campaign that Mr. Hughes launched against the enemy firms.

The task of carrying out the Government's policy was entrusted to Mr., now Sir, J. M. Higgins. It is too soon after the War to discern all the motives that actuated a certain course of action at that time. The Labor party, which at that time stood solidly behind Mr. Hughes in his anti-German crusade, had visions of bringing about the nationalization of the base-metal industry of Australia. So it stands to the credit of Higgins that while striving for control by the State of this vital wartime industry, he evolved an instrument that enabled that control to be exercised without creating a Government department or bringing nationalization one whit nearer. The scheme in all probability did not work quite as Higgins expected. The creating of the Metal Exchange and the establishment of a system of registration of sales and contracts enabled the Government to block German attempts to retain its hold on industry through indirect means, and also prevented other countries from stepping into the shoes of the German metal firms. It also stimulated the enlargement or building of plants for the smelting and refining of base metals in Australia. These became a boon to the producers of lead, copper, and tin when high shipping-freights prohibited the export of anything save the refined metals. The British government also was put in the position of being able to purchase *en bloc* the exportable surplus of lead and copper, as well as of wolfram and molybdenite, and so could counter to some extent the moves of other countries to squeeze the last cent out of it for metals. But control did not pass entirely out of the hands of the Government into those of the Metal Exchange, and consequently the evils of political and bureaucratic interference still remained, although they were not as prominent as in other directions, especially in the matter of fresh issues of capital, to which reference will be made in another paragraph.

The reason of this inability to realize the idea of the

self-control of industry was primarily owing to a mutual distrust of the various mining groups of one another. They were not prepared, when they had the chance so to do, to leave themselves in their own hands. Whereas they could at the outset have rid themselves through the Metal Exchange of Government control almost entirely, rather than put themselves at the mercy of one another, they preferred to invite political and bureaucratic exploitation. Another reason was, as must always happen in any democratic form of government, that the power went to the stronger group or groups; the smaller producers, whose petty jealousies prevented them from organizing, failed to take any means to prevent being out-weighted, although all the time they were most vociferous in complaining against exploitation by the more powerful groups that had come together. The outcry gave the politicians an opportunity to claim the right of interference. This tended to make the small producers the instrument by which some of the middlemen, who found themselves cut out of the trade by the co-operative selling organizations formed under the aegis of the Metal Exchange, attempted to work their way back. Finally, it is not assured that Higgins, although he created the Metal Exchange to avoid political and bureaucratic control, was prepared himself to hand over completely the power he was wielding as Government adviser to the instrument that he had framed. Still, the Metals Exchange did good work during the War, and if the Government withdraws its support from it now that hostilities are over there is every probability that some of the leaders among the mining companies will continue to associate themselves with it.

Another public part played by one or two leading citizens was to control, under the Federal Treasury, the issues of fresh capital. These gentlemen may have had something to do in the way of advising the Government in its price-fixing campaign. So far their recommendations and energies have not been fully disclosed, but the folly of interfering with industries, even when the men to do the interfering are actuated with the best motives, can be demonstrated. The effect of the regulations to control issues of capital was lopsided. For instance, permission was given to one company to double its capital. The only reason to suggest itself for such action must be that its shares stood high in the market, and then refusal was given to another company to register a new company as a part of an option bargain with the mine vendors—although the new company was to test a large low-grade gold deposit. The effect of the interference by Treasury officials was to drive the prospector from the back country. If he could not interest the promoter, where was he to get the cash with which to go

on or to reward him for pioneering in one of the most barren and god-forsaken regions in the world! The whole arrangement was stupid, so stupid that one can only connect it with the regulation that prevented the free sale of zinc concentrate to Japan, which at the time was assisting in patrolling the Pacific and ensuring the safety of Australia.

So it can be affirmed that the gold mining industry of Australia is today worse off than ever before. It suffered first of all from the withdrawal of men from work in order that they might serve their country at the front. Then it was affected by the high price of supplies, these in some instances rising to 200 or 300% above the pre-war rate. Moreover, the fact that a standard price ruled for gold in the Empire and that the Government for long forbade exportation, in order that it might add to the backing of the ever-increasing note-issues, meant that the buying price of the pound sterling dwindled astonishingly and as the Arbitration Court put up wages it was no wonder that mines began to be shut-down. Worst of all, through the blotting out of the promoter, no prospectors were in the open to continue the search for mines. One official controller, when questioned regarding this phase of his activities, seemed to fear that there would be some financial cataclysm if the modest little promoting syndicates so common in Australia with a capital of a few thousand pounds were permitted to be formed, whereas the waste and expenditure in a dozen other directions, where control ought to have been exercised, was almost without limit. Even now, when the Prime Minister is preaching that the only thing that can save the nation is production, and when everyone would welcome the discovery of a new goldfield, the restrictions remain. It is always too difficult to shift a governmental department once it has been established. That applies to the office established to control the issue of capital in Australia during the War.

However, it is interesting to note that a party of men who have been working on Hampton Plains, some 25 miles south of Kalgoorlie, have been responsible for a boom in gold mining. This is due in part to the nearness of the find to the Golden Mile of Kalgoorlie, and in part to the popular belief that the discovery is a continuation of that famous series of gold mines. What helped to bring the claim into prominence was the fact that Richard Hamilton, Mr. McDermott, and two or three other of the biggest mining men in Kalgoorlie took an option over the property at a high figure. Since that was done they have carried out a vigorous development policy and high-grade ore has been opened up by them down to a depth of 100 ft., at which point driving north and south along the line of the ore-shoot is going on. The lode is 25 ft. wide and assays several ounces per ton, but it has yet to be proved that the richness persists into the sulphide zone. That has been the crucial point with all other mining 'shows' in the district. Hundreds of new claims have been pegged out on the line of the lode, or east and west of it, and 'shows' that under other circumstances would not attract attention have

been taken under option for £10,000 or £20,000 each. Apart from the fact that the discovery in the main shows richness, so far none of the other claims among the host pegged out has given what can be even regarded as a satisfactory account of itself.

The old goldfields of Australia are slowly dying. Charters Towers and Gympie, in Queensland, are 'has-beens' and it is copper rather than gold that brings grist to the shareholders of the Mt. Morgan mine. In New South Wales, the gold-dredging industry is done and the yield of the precious metal is almost negligible. Victoria has suffered greatly; deep-lead mining is at a standstill; although there are deep gutters awaiting exploration, the results from the mines that have struggled along are so disappointing and the calls for capital are so incessant that there is still little inducement to continue or to engage in fresh ventures. So far as quartz mining goes, the story is the same; an ambitious attempt was made not long ago to revive Bendigo by merging a number of the claims in the central area; it was hoped that costs would be cheapened and the output so enlarged that profits would come with better organization, but results to date have been disappointing. Bendigo bears testimony to Mr. Rickard's opinion that with depth gold values fade. It might have been better if the promoters of the merging project had devoted more of their attention to the side-lines of the 'saddle reefs', but in all probability enterprise in that direction was checked by the disappointing results obtained from operations on the main lines where the yield had been expected to be good. Nowhere in Victoria have finds been made to fill the gap occasioned by the closing of exhausted properties. The same thing has been going on in Western Australia. Mining at Kalgoorlie is on the decline; the Westonia field, which was at its zenith when the War broke out, appears to be petering out. Perhaps Hampton Plains may bring a few new mines into existence, but, so far, only one claim has made a good showing. Still, it is interesting to note that the result of the boom in that locality has led to the fitting out of scores of prospecting parties, thereby indicating how an active market will stimulate mining activity.

What has been said about gold mining applies to base-metal mining. Prospecting has been almost a dead letter save for the secondary minerals, such as molybdenite, wolfram, and antimony. The high price ruling for the first two, and later on for arsenic, attracted men into the field and there has been a notable increase in output, especially of molybdenite. In this connection the progress made by applying the flotation process to the recovery of this mineral is noteworthy. But mine operators are anxious; they do not know whether prices are likely to collapse now that the War is over.

Tin mining is another fading industry; despite that fact it is said that capital is forthcoming for starting a tin-plate industry in Australia. That this is possible is because of the magnificent steel and iron works the Broken Hill Proprietary Co. has established at Newcastle to treat the ore from the Iron Mount in South

Australia. This enterprise is by far the most important industrial project launched in Australia for many years. The works are extensive and embody the very latest improvements in manufacture. The high prices ruling for iron and steel during the War enabled the company to earn large profits, and, with the wisdom that has characterized the control of its affairs, the directors used a large proportion of their surplus to expand this enterprise. Now a strong agitation is maturing to give the company, and the nest of enterprises being built round its central works, the benefit of strong protective duties, although it is not so long since it was said that the richness of the ore, the excellence of the appliances and their splendid arrangement, as well as the close proximity of the works to cheap coal meant that no tariff aid was necessary. The dread of dumping by the United States and by China and Japan is the reason given for the request, which is sure to be considered favorably. It may be added that the success of the enterprise has led the Queensland labor government to venture in the same direction. Large deposits of iron and coal exist in that favored State and so the Government, if it continues to live, will be enabled to carry out one of the cherished ideals of the Labor party there—the nationalization of the iron and steel industry.

With no fresh discoveries to add to the resources of the Commonwealth, the output of lead, silver, and zinc has been restricted mainly to Broken Hill, because the few mines of this kind at work in Tasmania, Queensland, and Western Australia were so small that they were not serious factors. This output, as stated, has been under the control of the Metal Exchange. Mining at Broken Hill has gone on fairly steadily, the mines making splendid profits, thanks to war prices. Outputs were less than before, partly because of troubles with labor in various directions. The field is slowly being exhausted; at mines like the Broken Hill Proprietary, Block 14, Block 10, British Junction, and Junction North, one can fairly well see the end of the reserves. The present big mines are the South, the North, and the Zinc Corporation's South Blocks mine. These claims are at opposite ends of the line of lode and get ore on the pitch from the mines either to the south or the north of them. They are all huge concerns with many years of life ahead of them. In point of fact, they really are the backbone of the proposed Electrolytic Zinc Co., which is starting the manufacture of zinc electrolytically in Tasmania, where cheap water-power is available. The industry is being backed by the British government, which has promised to take a large proportion of the zinc products of Broken Hill for ten years after the War at "a satisfactory price". The same people are connected with the Port Pirie lead smelter, into which they bought from the Broken Hill Proprietary on terms that gave them a dominating interest. It is said that they have altered the establishment almost out of recognition, with the result that a great saving in treatment is assured. Important metallurgical experimenting has been done in regard to the better treatment of lead-zinc ores, and it is rumored that

a method has been devised that almost constitutes a technical revolution.

Copper mining has had many vicissitudes, but it appears to be overcoming them. Mount Lyell, Mount Morgan, and the north Queensland group still represent the giants of the industry. The end of Mount Morgan apparently can be foreseen, although it has years of life ahead. Mount Lyell goes on smoothly under Robert Stiehl's management, with shoots of ore still opening up in the North Lyell and the Comstock claims alongside. The same company is proceeding with its development at Mount Reid and Rosebery, where it owns a group of claims having large resources in high-grade zinc and lead ores. The financing of the mines has been done so far by the Mount Lyell company, but it contemplates an expenditure of £750,000 on electrolytic works, so that an appeal will have to be made outside, possibly a debenture issue. In Queensland the labor element has been most aggressive and it is clear that mines there cannot pay under present-day conditions with copper at £80 per ton. The best news from there has been the opening up of the Mount Oxide mine, where some 250,000 tons of 10% copper ore is proved. This mine, however, wants a railway to bring it into touch with the world.

The point of all this review is that the mining industry in Australia is depressed owing to the operation of three factors—high cost of labor and supplies, Government interference, and above all the lack of developments in any old or new centre. It is fitting to say a word or two, before ending, about the development of the brown coal industry of Victoria, in which, with two or three others, I have had much to do in stimulating the Government of Victoria to action. These deposits are larger than those of Saxony and are quite as accessible to the miner. In quality they are equal, if not better, in grade. The drawback to their development by private enterprise has been the determination of the State Legislature that the State must control the supply of electricity. Strikes in Newcastle cut Victoria from its supplies of fuel, and with war, labor, and repatriation problems looming in the distance, a small body of enthusiasts set to work to educate public opinion as to the value of this resource to the State. The matter has now been advanced so far that the State is practically committed to the carrying out of the project of developing the coal for power purposes at a cost of fully £1,500,000. The question of the utilization of the coal for by-products will come up later.

THE asbestos-bearing belt of eastern United States extends from Quebec, Canada, to the State of Alabama, a distance of about 1600 miles. The northern part of the belt in Quebec contains the world-famous deposits of chrysotile asbestos, and these deposits extend southward into Vermont. From Vermont southward, practically all the asbestos found is of the amphibole non-spinning type. Such fibre has been worked in Massachusetts, Connecticut, Maryland, Virginia, and Georgia. The occurrence near Great Falls is remarkable in the fact that it is chrysotile instead of amphibole asbestos.

The Two Professions of Mining Geology

By AUGUSTUS LOCKE

In offering this paper I have two principal purposes in view: (1) to indicate a confusion existing in the public mind through the use of the term 'mining geologist' by two distinct professions; and (2) to discuss certain disadvantages caused by this confusion.

The accomplishment of these purposes will necessitate plain speaking; it will involve an ingredient of caricature and ridicule. But if there are statements which seem discourteous to honorable names, I disclaim any intention of making them so. The bearers of those names are justly famous in a certain branch of mining geology, so-called. If there is another branch, into which they sometimes venture and in which some of them are not worthily proficient, then there can be no objection to an examination of the facts: indeed the very men involved will be among the first to admit the facts, once they are established.

The two professions (or two branches of mining geology) to which reference is made are those concerned respectively with mining litigation and with the search for ore. For convenience the work of the first may be termed 'court' geology and the work of the second, 'ore-hunting' geology.

The belief that these are, in fact, two distinct professions is supported by several arguments. The ore-hunting geologist, ideally, possesses a judicial temperament. He has the power of poised and suspended judgment—of seeing each object from various viewpoints; he has a mental suavity; he can understand and welcome thoughts born of other minds. He has both imagination and patience; he is vigorous without being controversial. He has an active ingenuity in the search for truth; he will travel far to complete a concept, or to gain impressions from a distant ore deposit and apply them to the study of one that is nearer home. He possesses not only honesty of purpose, but ability to distinguish the source of an idea; he will see his own motives, and will know unerringly when some ill condition of the body has cast a shadow on his mind. He will have his principal professional interest in geological reasoning and its application to mining. He will prefer the discovery of an orebody to the acquirement of a fortune in money.

As a matter of fact he cannot have all these characteristics, but he must aspire to them, lest he be stamped into one-sided conceptions. The complications of his subject, and the youth and incompleteness of its technique make a thorough-going judgment exceedingly difficult. Prejudice is the ore-hunter's devil, and prejudice tends eternally to fill in where knowledge is deficient. The man of dignified and grave demeanor is urged from without and within to use his convincing personality,

which is always available, in place of that logic which, despite laborious efforts, must often say, "I do not know". Judicially written geological reports will usually contain confessions of ignorance. Rare indeed are such reports and common are those that, in a logical analysis, fail to carry conviction—that, in effect, rest on some obscure prejudice.

The court geologist, on the other hand, needs the mind of an advocate. He must be "dextrous and able in explaining the grounds of his opinion".¹ He is suitable for court work in proportion as he has the ability, though taking sides and maintaining a partisanship, to convince the Court. It is not a scientifically sound structure that he must aspire to, but one that looks good to the Court. His reasoning may be defective; for the Court will apply no very stringent tests; in geology, the Court is no more than an amateur critic.² It is not so much logic as personality that will speed the argument. If the witness bears a look of wisdom and deliberation, if he has a convincing address, he will go far toward victory.

During a trial in court, prejudice jumps to the front. The trial is a game. The witnesses are sportsmen; they act with a superb team spirit; they will do or die. Success promises a delight that awakens a predominant motive. The formal-looking models and maps, the long night conferences, the hurried consultations, the interminable rehearsals of evidence—these are controlled by that motive: they banish calm thought. Who can be both advocate and judge?

Let us consider the Elm Orlu v. Butte & Superior lawsuit of 1915. On either side were five principal geological witnesses. A shrewd spectator said, "Here are five of the most eminent geologists in the United States employed by the Elm Orlu company, and five others equally eminent employed by the Butte & Superior company. This five, to the man, are all of one opinion; that five, to the man, are all of the opposite opinion."

This situation unquestionably signified not dishonesty, but merely prejudice. It signified mere prejudice, too, even when there developed plain contradictions regarding easily ascertainable facts, and when there appeared two sets of maps showing in the same workings differences that the ore-hunting geologists could not but see with astonishment. One could predict the burden of an answer, the general effect of a piece of evidence. "Are the Jersey Blue vein and the Rainbow lode contemporaneous?" Mr. Winchell's chorus says, "No!" Mr. Finch's chorus says, "Yes!" But why the chorus? Because a single affirmation of an opinion is far less con-

¹Hazlitt, 'Table Talk', Essay IV.

vincing than its five times reiteration, gravely performed by men of sober mien.

How, it will be asked, is such a result compatible with honesty? I consider it entirely so. To a given witness, sustaining a particular contention, the prejudice seemed to lie wholly with his opponents: he asked himself conscientiously again and again how these able men could have achieved such an inconceivable bigotry. And yet, among the complicated elements of an argument, where, in case after case, the weight of a straw would be decisive, he was himself putting the straws all on one side; instead of letting them lie where they fell, as the scientist must do, he unconsciously shifted them a little, and then, proudly and confidently, showed the emphatic result.

In reality, prejudice of this sort, wholly honest, yet from the logical standpoint unfair, is a natural condition even among technically trained men. William James has numerous discussions touching upon it: he vividly describes 'apperception', that process by which a given object makes wholly different effects on different minds because in entering those minds, the impression is engulfed in a variety of mental environments.² "It is the fate", he says, "of every impression thus to fall into a mind preoccupied with memories, ideas, and interests. The self-same person, according to the line of thought he may be in, or to his emotional mood, will apperceive the same impression quite differently on different occasions. A medical or engineering expert, retained on one side of a case, will not apperceive the facts in the same way as if the other side had retained him."

It is not, then, a matter of honesty that separates the court geologist from the ore-hunting geologist, but a matter of temperament and circumstance. I am writing with no intention of condemning the motives of the court geologist, for his motives are both natural and useful. One who condemned them would be little more than a cynic—he would condemn lawyers, for example, and salesmen, and men who, for an idea, risk their lives in battle. Court geology is often not geology at all, but a matter of legal word-definitions; or, geologically considered, it depends less on logic than on feeling: it is unscientific—that is the burden of my argument.

For court work and for ore-hunting, the faculties needed, then, are sharply different. In so far as a man is, by nature and training, suited to the one profession, he is, in large measure, unsuited to the other. If he be the calm and patient investigator, willing to postpone his conclusions till the time of their maturity, he is little fit for the court-room. If he be the ready and resolute fighter, fond of the contest for itself, a wit-snapper, shrewd in avoiding traps and skillful in returning the wily answer, he is not the best man for the profession of ore-hunting. Perhaps in these days, when the profession of ore-hunting is young, the court-geologist may sometimes perform in it relatively well; but it is by nature a profession foreign to his abilities, and a little while hence he will have no place in it.

²'Talks to Teachers', p. 157.

Perhaps, again, there is now and then one who can actually handle both professions well; who, being of judicial mind, so carefully studies a case in advance that he is certain of his ground before he enters upon it; who is able, therefore, to support his contention calmly. But such a man must have uncommon wisdom and virtue. It is no easy task to choose the right side of an apex question. In the Butte case referred to, a choice would necessitate very extended work. A witness may desire to choose correctly, but no mining company will permit him months of indecision when it can secure men who will choose in a day or a week. Those incapable of speedy and favorable decision on point after point, despite complexities, are condemned as poor witnesses. Or, they are shrewdly confined by their more experienced teammates to selected portions of the case where their testimony will be unequivocal. Or, at last they are caught up in the enthusiasm of the game: even the patient scientist will strongly tend to yield and become biased in his thinking when hustled about by the exigencies of a court trial.

When it is realized that ore-hunting geology needs a minimum of prejudice and that court-geology needs, if not a maximum, at least a substantial ingredient, it will be understood that the two cannot mingle advantageously. But in the past they have mingled inextricably. Many of the more famous mining geologists doing commercial work have been chiefly court geologists. To them the owners of mining companies have turned, regardless of the kind of geological study needed. And they have done this naturally enough, making no fine distinctions between two geological professions and preferring the well-known man to the obscure. And they have done it for another reason: ore-hunting geology, though in essence a distinct profession, has scarcely yet established itself as such. Its personnel is small; its technique is somewhat crude; its outlines are hazy; its possibilities of achievement are little known. The fact that much of its work has been performed by men saturated with court work has helped to keep it in this condition. And the very existence of this condition has caused court geologists to do its work. The effect has been to carry the prejudices of the advocate into ore-hunting geology. It has delayed and is today delaying the development of geology as a useful instrument in mining. While at the first ore-hunting geology grew in a measure out of court geology, now the parent is a sore impediment to the child.

The time is approaching when ore-hunting geology can assert itself as a distinct profession. That time will come the quicker if those geologists who have the judicial temperament and who are employed in ore-hunting will avoid court work, in the sense here discussed, altogether. It will come the quicker, too, if the judge in some conspicuous apex case of the future will demand the employment of geologists not to stand beside the respective litigants but to advise the Court. That case would be one in which the judicially minded geologist could, with all propriety and cheerfulness, engage.

Statistical Review

Production of Metal Mines for 1919*

Colorado

The mine output of gold, silver, copper, lead, and zinc in Colorado for 11 months of 1919 and the estimated output for December, according to data compiled by Charles W. Henderson, amounted to \$9,892,000 in gold, 5,630,000 oz. of silver, 35,650,000 lb. of lead, 3,400,000 lb. of copper, and 52,300,000 lb. of zinc, having a total value of \$22,522,000 as compared with a production in 1918 of \$12,751,718 in gold, 7,063,551 oz. of silver, 65,960,760 lb. of lead, 6,277,332 lb. of copper, and 89,133,901 lb. of zinc, having a total value of \$34,160,172. This estimate shows a decrease of \$2,860,000 in gold, 1,430,000 oz. of silver, 32,160,000 lb. of lead, 2,877,000 lb. of copper, and 36,834,000 lb. of zinc. Even at the increased value for silver of \$1.11 (average) as compared with \$1 in 1918, the value of the silver produced in 1919 was \$6,249,000 as compared with \$7,063,551 in 1918, and with the lower average prices for lead, copper, and zinc there were respectively decreases of \$2,651,000, \$915,000, and \$4,398,000.

Naturally the lead-copper plants in the State were not operated at full capacity. The Globe plant ceased to receive ores in April 1919, but the Leadville, Pueblo, Durango, and Salida plants were worked at reduced capacity. The United States Zinc Co.'s zinc-retort plant at Pueblo was operated at greatly reduced capacity. The River Smelting & Refining Co.'s plant at Florence continued to treat low-grade zinc-lead-copper ores from Colorado only. The Western Zinc Concentrating Co.'s plant at Leadville was operated at increased capacity on Leadville zinc-carbonate ores, and the Ohio Zinc Co.'s zinc-oxide plant at Cañon City was also operated at increased capacity on zinc-carbonate ores from Colorado, Nevada, and Utah. The Empire Zinc Co.'s magnetic-separation mill at Cañon City was operated steadily on Leadville zinc-sulphide ores, but the Western Chemical Co.'s magnetic-separation wet-concentration mill, treating similar ores, was operated for only a part of the year, although the Western Chemical Co.'s sulphuric-acid plant was active on pyritic ores and also made considerable electrolytic zinc. Copper ore and matte and cyanide precipitate were shipped from Colorado to the smelter at Omaha and some copper ores were shipped to plants in Utah. The quantity of zinc ores shipped to zinc smelters and zinc plants in Kansas, Oklahoma, and Eastern States decreased heavily. Shipments of manganese, which had assumed considerable magnitude in 1918, ceased with the expiration of contracts on July 1, 1919.

Cripple Creek produced \$5,830,000 in 1919 as compared with \$8,119,747 in 1918, a decrease of \$2,280,000.

The Golden Cycle roast-cyanidation mill at Colorado Springs, which treats about 95% of the high-grade ore shipped from Cripple Creek, was operated steadily except for a three weeks shut-down during the coal strike in November, when it gave its coal to the city of Colorado Springs. In October the Vindicator washing and flotation mill at Victor was closed, so that less ore was available for the Golden Cycle mill. The Portland Independence cyanidation-concentration mill at Victor was the only mill actively operated throughout the year in the Cripple Creek district.

Lake county, chiefly Leadville, but including also Lackawanna Gulch, Sugar Loaf, and St. Kevin lode districts and the Arkansas River dredge district, produced \$624,000 in gold, 1,515,000 oz. of silver, 10,500,000 lb. of lead, 800,000 lb. of copper, and 37,000,000 lb. of zinc, having a total value of \$5,700,000 as compared with a production in 1918 of \$43,239 in gold, 2,290,121 oz. of silver, 1,626,531 lb. of copper, 22,469,915 lb. of lead, and 46,715,736 lb. of zinc, having a total value of \$9,381,610. Early in 1919 the low price of zinc and lead caused the Leadville operators to post a reduction of \$1 per day in wages which the miners met by a walkout; the result was a cut of 50 cents per day in wages and the closing of several large properties. The long productive Western Mining Co.'s properties were closed at the end of 1918. The Town Mines Co. continued operations throughout 1919.

Despite the removal of the pumps from the lower levels at Aspen early in the year, there was a production of 647,000 oz. of silver and 5,000,000 lb. of lead, making an increase for silver but a heavy decrease for lead from that district.

In the San Juan region, the Telluride district was the only one to maintain its production at normal, the output being \$2,100,000 of gold and 1,380,000 oz. of silver, but the contemplated closing of the Liberty Bell mine and mill, which has been in continuous successful operation since 1896, foreshadows a decrease in production in that camp for 1920. The Tomboy Co. at Telluride built a new mill and the Smuggler Union Co. added to its plants during 1919, but the increase in the output of these companies must be considerable to equalize the loss of the Liberty Bell. At Silverton the production has been less than it has been for several years. The fire which burned the Sunnyside office buildings and the miner's boarding and hotel buildings early in 1919 prevented that large producer from starting complete operation. The Iowa Tiger mill continued operations and made large production. At Ouray, the Camp Bird Co. did much exploring work on the vein at the end of its new low-level adit but did not start milling. The Atlas

*From preliminary reports of the U. S. Geological Survey.

and Mountain Top mines were in operation, and much development and some shipments were made at Red Mountain. Mines in La Plata county made very little production, although development work was done during the summer. Dolores county continued to ship copper ore from Rico, but no lead-zinc ore. Mineral county which had produced, at Creede, a greatly increased quantity of silver in 1918, showed a considerable decrease in 1919, as one of the largest lessees abandoned work there and one of the other large properties was not so productive as it was in 1918. The production in Hinsdale county again dropped to only desultory shipments of miscellaneous ore.

Early in 1919 the Wellington Co., at Breckenridge, found itself without a market for its zinc concentrate but continued operation for a few months, storing its concentrate. In September this company began shipping its stored concentrate and shipped also some iron-sulphide ores. The production of zinc from Summit county, therefore, which was 15,696,264 lb. in 1918, was only about one-third as much in 1919. Dredges in Summit county produced \$150,000 in gold in 1919 as compared with \$451,000 in 1918.

The mines at Red Cliff, Eagle county, were active only during the early part of the year, but development only was carried on at the zinc mines during the last half of the year.

Production in Gunnison county was confined almost entirely to the zinc produced by the Doctor mine, on Spring creek, from which there were increased shipments of zinc-carbonate ore, and to small shipments of gold-silver ore from Iola and from Ohio City.

Boulder county increased its output of silver from 157,000 oz. in 1918 to 203,000 oz. in 1919 from the Yellow Pine at Sugar Loaf, the White Raven at Ward, and from the mines at Caribou. The mines in Gilpin county were not active, and the closing of the Argo mill, and its associated Tremont (Gunnell) mine at the end of the Argo adit, reduced the production greatly. This county produced \$83,000 in gold and 72,000 oz. of silver. The Becky Sharp mine produced considerable gold ore, and the Gilpin Eureka shipped amalgam bullion and concentrate.

In Clear Creek county the low price of lead and zinc closed the principal producing mines at Silver Plume in May, 1919, and thus cut off the usual large silver contribution from that camp. There was a production from this county, however, of \$226,000 in gold and 334,000 oz. of silver. Early in the spring the new Colorado Central mill, near Georgetown, increased its capacity and throughout the year contributed considerable silver in concentrate derived from the treatment of material from the Equator dump. The mills at Idaho Springs were not active in 1919, for the Argo and Jackson were closed, and the Hudson and Newton were operated only on part capacity. The Little Mattie mill resumed operations at the close of the year.

Park county made appreciable increases in the output of gold and silver.

Idaho

The value of the gold, silver, copper, lead, and zinc mined in Idaho in 1919, according to the estimate of C. N. Gerry, was about \$19,376,000, a decrease of \$17,146,000 from the value in 1918. The decrease in the quantity of all the metals produced but gold, as well as in the total value of the output, was decidedly great, and was due in part to the difficulty in marketing copper, lead, and zinc, to the lower prices for these metals, and to the high cost of labor and supplies. In August a labor strike in the Coeur d'Alene region prevented shipments from many of the large mines near Wallace. Fortunately labor troubles failed to close the mines near Kellogg, and the Bunker Hill smelter and refinery at Bradley were active throughout the year, though not running at full capacity.

GOLD. The mine output of gold in Idaho was valued at \$703,000 in 1919, a value close to that of 1918. The largest output of gold was made by the Gold Hill & Iowa property, in Boise county, though the dredge at Murray, in Shoshone county, produced considerable gold. In Boise county no dredges were operated, and in Lemhi county there was only a small dredge output.

SILVER. The mine output of silver decreased from 9,172,340 oz. in 1918 to 5,701,000 oz. in 1919, nearly 38%, an unusual decline, and the value decreased from 39,172,340 to \$6,340,000. Decreases amounting to 300,000 oz. or more were reported by the Hercules, Morning, Hecla, and Tamarack & Custer mines. Smaller decreases were reported by the Bunker Hill, Caledonia, and Gold Hunter. The largest silver producer of the State was the Bunker Hill & Sullivan mine, at Kellogg, which was followed by the Hecla mine, at Burke. Other large producers of silver were the Morning, Caledonia, Gold Hunter, Hercules and Tamarack & Custer mines. The mines in the Coeur d'Alene district produced about 4,800,000 oz. of silver, or about 84% of the total of the State.

COPPER. The mine output of copper decreased from 6,333,888 lb. in 1918 to 3,100,000 lb. in 1919. The value of the output decreased from \$1,613,870 to \$591,000. The Empire Copper Co., at Mackay, was the largest producer of copper, but the output was only about 40% of that in 1918. The National Copper mine, near Mullan, produced considerable copper concentrate, but was closed late in the year. The shipments from the Richmond mine, near Adair, were considerably reduced. Smaller shipments came from Lemhi and Custer counties.

LEAD. The mine output of lead, which is the most abundant metal in Idaho, decreased from 294,695,993 lb. in 1918 to 184,000,000 lb. in 1919. The average price was somewhat lower, and the value of the output decreased from \$20,923,416 to about \$10,529,000. The Bunker Hill & Sullivan mine made the largest output of lead; the Hecla, Morning, and Hercules were the next largest producers. Considerable lead was also produced by the Tamarack & Custer, Gold Hunter, Consolidated Interstate Callahan, Caledonia, and Sierra Nevada

mines. The Coeur d'Alene district produced about 172,000,000 lb. of the total output of lead. In other districts of the State large quantities of lead ore and concentrate were shipped from the Idaho Continental, Pittsburgh-Idaho, Latest Out, and Independence mine, near Ketchum, in Blaine county. Large shipments were also made from the old Minnie Moore mine, situated near Bellevue.

Zinc. The mine output of recoverable zinc in Idaho decreased from 45,161,712 lb. in 1918 to 16,565,000 lb. in 1919. This decrease of over 28,596,000 lb. was largely due to high costs and to the lower price of spelter. The largest decrease was reported by the Consolidated Interstate Callahan, which was active only about four months of the year. Large shipments of zinc concentrate, nearly equal to those of 1918, were made by the Morning mine, and shipments were made also by the Success and Frisco mines. No zinc ore was shipped from Blaine county.

The dividends paid by Idaho mining companies for eleven months of 1919 amounted to \$2,000,000.

Oregon

A preliminary estimate of the production of metals in Oregon in 1919, compiled by Charles G. Yale, shows a decrease in the gold and lead produced but an increase in the silver and copper. According to the mines report the output of gold in 1918 was \$1,270,165 and the estimated output in 1919 is \$1,072,661, a decrease of about \$197,804. The output of silver in 1918 was 107,323 oz., valued at \$107,323; in 1919 it was 211,523 oz., valued at \$234,790. The output of copper in 1918 was 2,451,016 lb., valued at \$605,401; in 1919 it was 2,638,714 lb., valued at \$501,355, an increase in quantity of 187,698 lb. and a decrease in value of \$104,046. The output of lead in 1918 was 10,601 lb., valued at \$753; the output in 1919 was 2000 lb., valued at \$114, a decrease in quantity of 8601 lb. and in value of \$639.

The decrease in the gold output of the State was due to some extent to the scarcity of skilled labor, to the increase in its cost, and to war conditions generally; but the main cause was scarcity of water and power for hydraulic, dredge, and deep mines. The water in the streams of the State was so low during the last two months of the year that hydro-electric power was entirely cut off from large properties, including the dredges, and was furnished for domestic use only. The larger dredges were shut down in November and December for lack of power, so that the dredges of the State, which ordinarily produce 57% of the placer gold and 22% of the total gold, produced, combined, only \$301,900, or \$85,840 less than in 1918, a decrease of 22%. The larger deep mines were similarly affected. Direct returns from all the dredging companies and the larger deep mines of the State show a general falling off in the output of gold for the year.

Returns from inquiries to postmasters, merchants, dust-buyers, and others reveal the fact that many mines in Oregon were idle during 1919. Higher wages in other industries attracted miners away from their regular op-

erations, and costs were so high that the smaller mining operations were unprofitable.

Most of the Oregon placers are worked by the hydraulic system, but the gold output of the dredges is greater than that of all other forms of placer-mining combined.

There are only about a hundred producing metal mines in Oregon and six of these produce 80% of the total output of all the metals mined in the State, and one of them produces 25% of the total value of the metals produced. These six mines are those of the Baker Mines Co., Cornucopia Mines Co., Homestead Iron Dyke Co., and the Commercial Mining Co., all in Baker county, and the Queen of Bronze Mining Co., in Josephine county. The only placer-mine in this group is the Powder River Gold Dredging Co.

The larger copper companies of the State, which are in Baker and Josephine counties, show some increase in output during the year, notwithstanding unfavorable conditions. The most productive county in the State in all metals is Baker, which produces nearly 80% of the gold and of the total value of all metals mined. Though less ore has been produced in Oregon during the last two years than in 1917, the average value of all the metals mined and treated has increased about 90% per ton. The relative rank of the counties of Oregon in the production of gold is as follows: Baker, Grant, Josephine, Jackson, Crook, Douglas, Umatilla, Clackamas, Lane, Malheur, Wallowa, Curry, and Wheeler.

South Dakota

Preliminary estimates, made by Charles W. Henderson, indicate that gold mines in South Dakota produced \$5,391,000 in 1919 as compared with \$6,565,337 in 1918 and 114,000 oz. of silver as compared with 159,202 oz. in 1918. The ores shipped to smelters contained only nominal quantities of lead and copper.

At the end of 1918 the Homestake mines and mills were operated at only 77% capacity. Shortage of labor continued during the year 1919, but production began to increase in April. Production continued steadily until September 25, when a fire was discovered on the 800-ft. level. Later this fire reached the 700-ft. level, and it was found necessary to flood the mine to the 600-ft. level.

While the mine was flooded—during October and November—the operations at the mines and mill were necessarily curtailed, but they were resumed December 1. The Mogul mill was closed during the later part of the year, and the Trojan mill was the only one that was operated without interruption. These three companies were the only large operators in 1919.

Texas

According to Charles W. Henderson, the Presidio mine, at Shafter, was in continuous operation during the year 1919. Small shipments of copper, lead, and zinc ores were made from the Van Horn and Sierra Blanca districts. The production for the State for the year was

540,000 oz. of silver and nominal quantities of gold, lead, copper, and zinc.

Utah

The output of gold, silver, copper, lead, and zinc from mines in Utah in 1919, according to Victor C. Heikes, had a value of about \$45,139,000, which represents a decrease of nearly \$41,000,000 from the value of the output in 1918. There were decided decreases in both the quantity and value of the metals produced. The average price of silver for the year was much higher than in 1918, but the prices of copper, lead, and zinc were much less. The mining industry was seriously affected by high costs of operation, lower prices of the metals, and a labor strike at Park City, which closed the mines of that region for two months.

Despite these difficulties the four smelting plants of the State were active throughout the year, but they were not operated at full capacity.

GOLD. The mine production of gold decreased from \$2,949,170 in 1918 to approximately \$2,070,000 in 1919, a decrease of nearly 30%. Most of the gold came from copper, lead, and zinc ores that were treated at smelting plants. No great amount of ore was either amalgamated or cyanided, though some ore was amalgamated at the Wedge mine and some was cyanided at the Deer Trail property, both in Piute county. More than half of the output of gold in the State came from the Bingham district, about one-fourth from the Tintie district, and the remainder from the Park City region and other camps. The largest producers of gold were the United States Mining Co., Utah Copper Co., and Utah Consolidated Mining Co., of Bingham.

SILVER. The mine output of silver decreased from 13,455,597 oz., valued at \$13,455,597, in 1918, to 11,569,000 oz., valued at \$12,865,000, in 1919. The Chief Consolidated mine at Eureka was again the largest producer of silver in the State, and the Tintie Standard followed closely. The output of the Tintie district was maintained, but decreases occurred at Bingham and Park City. In the Bingham district the United States Mining Co., Utah Consolidated, Utah Copper, and Utah Apex were the largest producers of silver, and at Park City the Silver King Coalition and the Ontario mine were large producers.

COPPER. The mine production of copper decreased from 227,169,630 lb. in 1918 to 123,626,000 lb. in 1919. As the average price was considerably less, the value of the output decreased from \$56,110,899 to \$23,242,000. The largest production of copper came from the Utah Copper property at Bingham, which yielded close to 9,000,000 lb. per month throughout the year, a decided decrease. Next to the Utah Copper, the Utah Consolidated was the largest producer of copper, followed by the Ohio Copper Co. and the United States Mining Co. In the other districts the principal producers of copper were the Ophir Hill, at Ophir, the Mammoth mine, the Centennial-Eureka, and the Tintie Standard, in the Tintie region, and the Bingham Mines Co. at Bingham.

LEAD. The mine output of lead decreased from 167,008,224 lb. in 1918 to 121,249,000 lb. in 1919, a decrease of nearly 46,000,000 lb. The value of the output decreased from \$11,857,584 to \$6,935,000. The largest producers of lead in the State were the United States Mining Co., Utah Apex, Utah Consolidated, Ophir Hill, Silver King Coalition, Tintie Standard, and Chief Consolidated mines.

ZINC. There was a decrease of about 77% in the production of recoverable zinc. The mine output decreased from 18,399,417 lb. in 1918 to 4,467,000 lb. in 1919, and the value of the output from \$1,674,347 to \$326,984. The principal producers of zinc were the United States Mining Co. and the Utah Apex Mining Co., at Bingham; the Judge Mining & Smelting Co., at Park City; and the Scranton mine, Tooele county. The electrolytic plant of the Judge Mining & Smelting Co., at Park City, was active for only six months of the year. Much of the decrease was due to the idleness of the tailing plants at Frisco and Midvale.

In 1919 the mines of Utah produced approximately 6,427,000 tons of ore, a decrease from 14,705,718 tons in 1918. Of this total, the Bingham district produced 5,913,000 tons, as compared with 13,607,650 tons in 1917. The production of the district is estimated as 56,000 oz. of gold, 1,600,000 oz. of silver, 117,000,000 lb. of copper, 54,000,000 lb. of lead, and 2,674,000 lb. of recoverable zinc. There was a decrease in the Tintie district, where the mines produced 265,000 tons of ore, exclusive of iron ore, as compared with 362,494 tons in 1918. The estimated production of the district was 25,000 oz. of gold, 6,800,000 oz. of silver, 2,800,000 lb. of copper, 24,000,000 lb. of lead, and a small amount of zinc. The mines that had an output of more than 1000 tons during the year were the Dragon, Chief Consolidated, Iron Blossom, Eagle & Blue Bell, Tintie Standard, Centennial-Eureka, Grand Central, Swansea, Mammoth, Colorado, Ridge & Valley, Empire, Bullion Beck, Gemini, and Victoria. The Tintie Milling Co. treated much ore locally and shipped bullion that contained gold, silver, and copper. Shipments of ore and concentrate from the Park City region in 1919 amounted to 63,325 tons, a decrease from 89,588 tons in 1918. Tabulation of the mines that made the largest production gave an estimated output for the district of \$64,083 in gold, 1,800,000 oz. of silver, 625,000 lb. of copper, 20,000,000 lb. of lead, and 1,350,000 lb. of recoverable zinc. The decrease was general, on account of the idleness of the mines during the two months of the strike. The mines of Ophir and Rush Valley districts produced 73,000 tons in 1919, as compared with 81,475 tons in 1917. The main producers were the Ophir Hill Consolidated and Bullion Coalition mines. About 18,250 tons of ore was shipped from the Big Cottonwood, Little Cottonwood, and American Fork districts, as compared with a total of 35,269 tons in 1918. In Beaver county shipments decreased from 43,426 tons in 1918 to about 9400 tons in 1919. A large production of bullion and concentrate came from the Deer Trail mine, in the Ohio district, of Piute county.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

HOLBROOK MINE TEMPORARILY SHUT-DOWN BY COPPER QUEEN COMPANY.

DOUGLAS.—A system of sanitation, begun late in 1919 by the Phelps Dodge Corporation at its Copper Queen smelter here, now is well on the road to completion. Sewer lines, costing about \$10,000, have been finished. Approximately \$20,000 more is being spent by the company on septic tanks, change-rooms, comfort stations, and other improvements. When completed the Copper Queen will be one of the most comfortable smelters in the country from the standpoint of employees. The changes were made in compliance with the Arizona law. The following officials of the Phelps Dodge Corporation conferred with P. G. Beckett, the new general manager, at a meeting held on January 16: Grant H. Dowell, manager of the Copper Queen branch; William H. Webster, assistant manager, Copper Queen branch; Joseph P. Hodgson, manager Morenci branch; W. B. Saben, assistant manager Morenci branch; E. M. Sawyer, manager, and R. J. Hutchins, assistant manager Tyrone branch; W. G. McBride, manager of Old Dominion; H. T. Hamilton, manager of the Moetzuma Copper company; J. S. Williams, Jr., representative of the Corporation in Mexico; H. M. Gallagher, general auditor; Col. H. H. Stout, superintendent Copper Queen reduction works; E. E. Ellinwood and John Mason Ross, legal department; T. H. O'Brien, director of industrial and public relations.

BISBEE.—The Holbrook mine of the Copper Queen branch of the Phelps Dodge company has been closed down and the men working in it have been transferred to the Sacramento and Gardner mines and a few to the Czar properties of the same company. The final days of activity were spent in repairing bad ground and filling old stopes. The present high cost of mine operations was found by the Corporation not to warrant mining the Holbrook low-grade ore. A revival of the copper market will mean the immediate re-opening of the mine, however. Of the 115 employees, including foremen, not one suffered in the transfer, either in loss of position or pay. The Holbrook is the second oldest shaft in the district, the Czar alone having priority over it.

JEROME.—United Verde Extension's cross-cut on the 1500-ft. level has entered the orebody previously disclosed by a winze run down to the 1700-ft. level. The ore carries an average of 6% copper, which is of lower grade than that encountered on the upper levels. The winze shows

ore of less value on the 1600 and 1700-ft. levels. Everything is pronounced in good shape at the Verde Extension by James S. Douglas, president of the company, who says that the only obstacle to good profit is the low copper market. The Shea Copper Co. plans a scheme of development which will involve driving a tunnel for 1200 ft. to open at a depth of 675 ft. the ore developed by the 320-ft. incline shaft. The tunnel will be started soon from the canyon east of the shaft and near the line of the Mohawk claim of the Copper Chief group. For the entire distance it will follow the east and west vein of silver-copper ore which runs across the Shea ground into the Mohawk and possibly into Jerome Bisbee. The United Verde Extension smelter has agreed to treat all Shea ores worth \$12 or more and it is believed the ore extracted in running the tunnel will pay for driving it. It will be necessary to timber the tunnel until it gets well into the solid vein matter and lumber for this purpose has been ordered. Upon its arrival the company will call for bids from contractors for the driving operations. Besides opening the mine 350 ft. below the deepest present working the tunnel will provide drainage and ventilation when connection is made with the shaft.

PATAGONIA.—The Flux Mining Co. now is negotiating for the purchase of a compressor plant and power-drills which are expected to be installed in the near future. This should speed underground development considerably. With hand work, because of the hard formation, little more than a foot per day can be made. With power-drilling machines at least five feet per day would be possible. Since breaking into the vein leading to the Glory Hole orebody on the 260-ft. level, it has been determined by the directors to block out all ore to this depth in order to estimate tonnage more accurately.

CALIFORNIA

STRIKE NOT PROBABLE IN GRASS VALLEY.

GRASS VALLEY.—Ever since the strike settlement of last summer rumors have been current of dissatisfaction with the terms of the agreement between the mine owners and the employees. No official cognizance had been taken by the Mine Workers' Protective League until recently, when the members thoroughly threshed-out the subject. The League denies any and all intentions to call a strike during the life of the agreement with the mining companies. That there are a few agitators in the community is admitted. It was only after repeated rumors of a

strike that the League took the matter up. The Western Federation of Miners does not maintain an organization in this county.

NEVADA COUNTY.—The Mine Workers' Protective League market has been doing a large business almost from the opening day. There is no discrimination; the general public is served as well as the members, but no reason has been assigned as to why the mining companies have failed to fulfil the conditions of the compromise agreement of last summer, by failure to furnish food supplies as well as clothing. The companies in at least two instances are conducting miners' stores, but have gone no farther. The Register and Receiver of the Sacramento Land Office recently decided a contest over 14 acres of land near Nevada City in the Round Mountain district, instituted by Thos. J. Nolan against the Central Pacific Railroad Co. in favor of the former, on the grounds that the land in question was more valuable for mineral than for agricultural purposes.

The Le Duc Mining Co. has been at work for 11 years driving a tunnel and doing other prospecting work on a 360-acre tract just east of Grass Valley without success. The company now intends starting a raise to tap the famous Blue Lead channel known to pass through the property. The South Star in the Rough and Ready district is again to be placed in operation. A permit has been granted authorizing the South Star Mines Co. to sell 50,000 shares of the capital stock at 25 cents per share. An option has been taken on the entire amount and the sum so raised is believed to be ample to re-open and operate the property. The mine was a producer until the vein was lost and then closed for a number of years. Last summer development work recovered the vein and opened ore which assayed around \$100 per ton and so encouraged were the owners that further active mining was decided upon. A. W. Johnson of San Francisco is president of the company.

COLORADO

VALUATION OF LEADVILLE MINES.—LEADVILLE ORES TO GO TO GOLDEN CYCLE MILL.

LEADVILLE.—The assessed valuation of the metalliferous mines in Lake county, as shown by the abstract of assessment filed by the County Assessor is \$3,577,270. The report in detail shows 36,749 acres of metalliferous mining claims valued at \$1,416,885 with improvements of the value of \$933,250; assessed value of output is certified as being \$1,226,885. As a tax asset the mines are second in importance to the 93.14 miles of railroad within the county which is assessed at \$1,968,040.

A contract for the treatment of gold ore from the Little Johnny mine calling for 6000 tons monthly has been entered into by the Golden Cycle Mining & Reduction Co., of Colorado Springs. The first consignment of seven carloads was delivered at the mill last week. The Little Johnny ore which was formerly treated at the Pueblo smelter of the American Smelting & Refining Co., is worth \$30 to \$25 per ton. The handling of Leadville

ores at the Golden Cycle mill, not only means economical treatment for Leadville gold-ores, but will result in the restoration of traffic over the Colorado Midland railroad. Negotiations are reported under way to make the Colorado Midland a transcontinental line, in connection with the Chicago, Burlington & Quincy or Rock Island roads and westward from Leadville over the D. & R. G. and Western Pacific.

CRIPPLE CREEK.—A station is being cut at the 1400-ft. level of the main shaft of the Blue Flag Gold Mining Co. on Raven hill, and with the work completed a contract will be let to exploit the territory to the south and east, toward the Cresson mine. A second cross-cut will be driven north-west under the orebody opened up at the 1200 ft. level on which development ceased when sinking was started about two years ago. Other exploratory work will be done in the upper levels. The cross-cut from the 1200-ft. level carried from the Blue Flag to the Mofat tunnel for air-connection on the War Eagle property to the north, has passed through ore for a distance of 70 ft. The vein is reported as being two feet wide and samples taken by the War Eagle Consolidated company gave returns of \$24 in gold and 13 oz. silver per ton. No work will be done on this vein until the tunnel connection is made and ventilation obtained.

A call has been issued for the annual stockholders meeting of the Portland Gold Mining Co., to be held at Cheyenne on February 16 for the election of directors. No change in the present board or officials is anticipated. The Lincoln Mines & Reduction Co., following a visit of directors to the mine, will, it is announced, enlarge its operations and to this end options have been negotiated on other properties. The Gasche-process concentrating-plant, now under construction, is to be hurried to completion.

IDAHO

EMPIRE COPPER OPERATIONS.

MACKAY.—News from the Empire mine, at Mackay, indicates that since the complete change of management, about nine months ago, rapid strides have been made in improving this company's position. During the War about \$1,000,000 in dividends was paid by the former management. This was done at the expense of good mining, for development was seriously neglected. The result was that on the signing of the armistice when copper broke to 14½¢, the corporation was nearly \$60,000 in debt, and most of the ore above the lowest level was exhausted.

About this time the control of the corporation was offered to the Nipissing Company, Ltd., and an extensive examination was made on behalf of the latter corporation by Morton Webber of New York. This examination occupied almost four months, as the Empire has 18 miles of underground workings. It is understood that the purchase price of the control was \$1,000,000. While the report recommended the mine as a profitable enterprise if given able management, owing to the run-down state of the property and because of the wholesale gutting, under-

gone during the War, when metal prices were abnormal, the two corporations failed to agree on a valuation and the deal collapsed.

Through the medium of the president of the Nipissing company the Empire directors employed Morton Webber as consulting engineer, and under the new management the property has been rapidly getting on its feet. One of the first things done was to employ John Linn, formerly of the Golden Cycle at Cripple Creek, as general superintendent. During the last nine months a new shaft has been sunk out of profits, and the audit of December 31 made by the accountants shows the property free from debt. Considering the fact that these important changes have been effected during a most unsatisfactory metal-market and a period of high cost of production, which has forced many properties to close-down or run at a loss, this is a highly satisfactory result.

An important change has been made in the policy of development. In the past, levels have been made at intervals of 100 ft., or even less. The distance between the Bullion level and the Cossack tunnel represents 800 ft. of undeveloped ground, through which the recurring ore-shoots pass. The new management intends to put in levels at intervals of 125 ft. By this means it is expected that the expense of one level will be eliminated. The cost of establishing one level in the Empire mine, including timbering, opening up of sill-floors, laying air-lines, and the other various items, is estimated at about \$100,000. Thus an important saving will be made. While it is possible that some ore may be lost by increasing the interval between lifts to 125 ft., the new policy would require to result in losing ore equivalent to \$100,000 before the former method would be economical. It has also been the custom in the past to turn over areas worked out on company account to lessees, and the new management feels that remnants of orebodies that may be left by reason of the increased space between levels can be extracted by lessees on a royalty basis, giving a profit to the Empire company, whereas the overhead expense in searching for remaining portions of ore, if done by the company, would probably not be profitable. During the last nine months the output from the mine has averaged 5.5% copper, 2.5 oz. silver, and \$1 in gold per ton.

MICHIGAN

U. S. BUREAU OF MINES PROGRAM FOR 1920 IN COPPER REGION.

HOUGHTON.—Efficiency rather than safety will be the principal subject of investigation by the U. S. Bureau of Mines in the Lake Superior district in 1920, according to the announcement by B. O. Pickard, district engineer. "In the past the work of the Bureau in the district has largely been concerned with teaching safety methods," said Mr. Pickard. "Now we are going to conduct a series of investigations looking toward improvement of the efficiency of mining methods."

Mr. Pickard will first investigate methods of stoping ore and later various features of underground storage of

explosives. Results of these investigations will be published by the Bureau for the general information of the mining industry of the United States. The Bureau meanwhile invites problems from the mining companies. It is at their service and wants to help in arriving at the most efficient way of solving all mining problems. In this it wants to co-operate with the companies' consulting engineers, seeking in no way to interfere with or hamper such officials.

This week the Michigan mine will commence work under improved operating conditions. Though they may

SMUGGLER-UNION MILL AT TELLURIDE, COLORADO

not be reflected in increased copper production during January, they should show in February, unless there are some unforeseen delays. Steam was turned on in the new shaft-house this week and the crushers are operating satisfactorily. The new storage-bin has been completed and will permit the accumulation of as much as 1000 tons in one lot in the rock-house. The mine is so isolated that trouble in securing cars often interferes with shipments and the new bins will take care of this situation. The property now has a working force of 230 of the highest-class miners ever employed in Ontonagon county. Conditions underground continue fair. On the 7th level,

west, the showings in the newer workings are up to standard.

Victoria will commence sinking again next week below the 28th level, through the big mass found in the lower workings. The 28th level cut into the lode January 16 and lateral work indicated good ore.

MONTANA

ACTIVITY NEAR HELENA.

HELENA.—The Blue Bird Copper Silver Mining Co. is installing a gasoline hoist on its property in the Scratch Gravel hills four miles north of here. E. R. Purnell, the superintendent, states that the shaft will be sunk to a depth of 200 ft. The Liverpool mine in Lump gulch, south of Helena, has been entirely unwatered, and shipments have begun to the East Helena smelter. A new electric hoist has recently been installed on the property, and the better hoisting facilities are expected to result in a larger tonnage of ore shipped. Other mines in Lump gulch shipping regularly are the Free Coinage and Little Nell. These mines, like the Liverpool, have recently been opened up after having lain idle a number of years. The increase in the price of silver has once more placed them in the producing class. About fifty men are employed at the Monarch mine. The new 100-ton concentrator is nearing completion, and is expected to be running before February 1. Operations have developed a large tonnage of silver-lead ore. C. E. Fryberger is manager. Another mine in this district showing great activity is that being operated by the Silver Pick Mining Co. This company has completed the installation of mining equipment capable of sinking to a depth of 800 ft. The property was formerly operated by C. L. Friederichs of Helena, and produced 170 cars of ore which gave a gross production valued at \$175,000. The ore is silver-lead carrying some gold and copper. The new company proposes to sink 200 feet.

NEVADA

RENEWED DEVELOPMENT ACTIVITY IN GOLDFIELD.

EUREKA.—The Mining & Development Co., which in October took over the Eureka Consolidated and Richmond mines in the Ruby Hill part of the district, has, in exchange for 100,000 shares of stock in the Ruby Hill Development Co., transferred to the latter company an option on 254,000 of 310,000 outstanding shares of stock. The option extends for three years. The Ruby Hill Development Co. is a Delaware corporation. It is reported that the company will reopen the old mines through the 1200-ft. Locan shaft of the Consolidated, the deepest in the Ruby Hill district. This shaft is filled with water. The surface equipment is steam driven. The production of both mines prior to 1896 is estimated at \$33,000,000 net.

GOLDFIELD.—The Yellow Tiger has \$20,000 in the treasury as a result of an assessment levied recently to provide funds for resuming work. Prospecting of the surface of the large area owned by the company has

started, principally on the Tiger and Red Lion groups in the southern part of the district. J. K. Turner, general superintendent of the Grandma, states that sinking of the shaft to 1000 ft. from the present depth of 830 ft. will be resumed. Assessment No. 6, payable immediately and delinquent February 25, has been levied for this purpose. During the past 10 months 764 ft. of work, practically all lateral, has been done at a depth of 815 ft. at a cost of \$18.37 per foot, which, according to Mr. Turner, "compares with other properties in the district much to the advantage of the Grandma". The work has resulted in the main body of the west-dipping shale being found and this is being prospected with a winze, but the east-dipping shale, which is the objective, has not been entered and no further search will be made for it until the shaft has been sunk to 1000 ft. Then a cross-cut will be driven west to it. The contact of the east-dipping shale and the latite has been prospected at many points in the district, only the Grandma, however, continuing the work. The Jumbo Extension orebody, which extended for a considerable distance above the shale, was found in exploring this contact. A winze has been sunk 100 ft. from the 910-ft. level of the Spearhead in a quartz-filled fissure in the alaskite. The fissure is from 2 to 4 ft. wide and assays as high as \$12 have been secured. The winze will be sunk to the limit of the capacity of the air-hoist being used before lateral work is started, which will be at about 150 ft. This work is being watched closely by engineers for nearby companies having deep shafts, as the finding of an important ore-shoot in the alaskite possibly would warrant further sinking of the Jumbo Extension and other shafts to the alaskite and a resumption of work in the alaskite by the Silver Pick. The Atlanta is drifting north and cross-cutting north-east on the 1450-ft. level of the Grizzly Bear shaft. The drift is following a narrow seam from which assays of \$12 are being secured and the cross-cut is being driven into the hanging wall of the vein, which heretofore has not been explored at this depth. It is rumored that the Merger plans to reorganize on an assessable basis and resume work, but A. H. Lawry, engineer for the Wingfield companies at Goldfield, says he has not been informed of such a plan. The Blue Bull is driving north from the main east cross-cut on the 250-ft. level. The vein is from 5 to 6 ft. wide and low assays are being secured. The Kewanas is driving north-east in a vein from which low assays in gold, silver, and copper are being secured. This is believed to be the same vein in which several hundred feet of drifting was done from a winze at greater depth and the drift will be continued to a point over this winze. The Atlanta, Blue Bull, and Kewanas are working in territory that practically is undeveloped.

UTAH

ALTA PROSPEROUS.—DAILY-WEST AT PARK CITY DEVELOPS OREBODY.

SALT LAKE CITY.—A hearing before members of the State Board of Equalization was given the coal-mine owners and operators of the State at the Capitol building

on January 20. The meeting was called for the purpose of discussing the taxation of coal mines. H. E. Klein, of the Utah Coal Producers' Association, stated that the unmined acreage owned by 74 different companies in Carbon county and one in Emery county, has been estimated to contain 892,005,500 tons of coal. The output of coal in Utah last year was 4,537,000 tons, so on the basis of present production, the unmined areas contain about 197 years supply.

ALTA.—The tunnel being driven by the Albion Consolidated company, from the Quiney tunnel of the South Hecla mine, to tap at depth the downward extension of

at the South Hecla, the Columbus-Rexall, the Michigan-Utah, the Alta Consolidated, the Cardiff, the Louise, and the Emma mine, encourages mining men of the district to predict a summer of highly profitable operation.

EVERETT.—A new find of high-grade ore was made recently at the Tintic Standard property on the 1250-ft. level of No. 2 shaft, according to E. J. Raddatz, general manager. The orebody is situated in virgin territory, 400 ft. east from the shaft. Samples of the ore show gray copper. Regarding the significance of the find, Mr. Raddatz stated that further work would have to be done to determine the extent of the orebody. Shipments of

NEW CONCENTRATING PLANT AT THE MONARCH MINE, WEST OF HELENA, MONTANA

the Wellington orebody, is progressing satisfactorily, according to G. H. Watson, general manager. About four feet is being made each day. At present the face is about one and one-half miles from the point where it leaves the Quiney tunnel. The Wellington ore deposit, containing high-grade silver, lead, and some gold, produced at various times during the past forty years. Expense of pumping, the inaccessibility of the old workings, and the fact that a new tunnel would save a three-mile haul in the handling of ore and supplies, convinced the company that this orebody could be more expeditiously and economically developed by driving a tunnel at depth. Consequently, the Albion tunnel, which should intersect the orebody at a vertical depth of 1400 ft., 700 ft. lower than the lowest level of the old workings, was begun. Physical conditions at the South Hecla mine are very favorable. East No. 1 stope, from which a silver-copper sulphide-ore is being taken, was never in better condition. Eleven teams are hauling ore from the mine to the railroad.

More satisfactory conditions have not prevailed in this district for the past fifteen years. The excellent outlook

late from this property have been increased. During the first 15 days of January, the output of ore averaged 240 tons per day. The spur track from the Tintic branch of the Denver & Rio Grande railroad has been completed up to the company's ore-bins, which will obviate the necessity of transporting ore by team, as has been the custom in the past. Preparations are being made to increase the output of ore.

MILFORD.—Mining activity has increased materially during the past few weeks in the Beaver County mining district. The Gold Crown property, which is just over the mountain from the Moscow mine at Frisco, has been opened to a depth of approximately 500 ft. by an incline shaft. It is reported that ore has been opened on four levels and that the width of the orebody is increasing with depth; the width on the deepest level being from four to six feet, with an increase in silver and lead content. The ore carries from $2\frac{1}{2}$ to 3 oz. of silver for each unit of lead. Ten ears have been shipped which have netted from \$1500 to \$2300 per ear. Present indications are that the Gold Crown ore is dipping to the west while the

Moscow orebody dips to the east. The Moscow, Red Warrior, and Combination properties in this district have been consolidated, and the new company already has men at work in the mines cleaning-up and repairing the tracks, tunnels, and shaft preparatory to active operations.

BRITISH COLUMBIA

SCHEME OF TREATMENT FOR THE SULLIVAN ORE.

NELSON.—The concentrator, designed by and erected under the supervision of W. J. Crook, of San Francisco, at the Emerald mine, near Sheep creek, has been completed. It is expected, however, that, owing to a shortage of water, it will be impossible to start operations until the spring. It had been the intention of the management to ship a quantity of crude ore to Trail this winter, but so far, there has not been sufficient snow to permit the transportation of ore. Last year 2092 tons of ore was shipped from the mine. Ore is being raw-hidged from a number of properties over the light snow. The Republic, at Lemon creek, which shipped 23 tons of high-grade last year, has a number of men and four horses at work; the Ottawa mine, near Slocan City has several men and horses moving ore, as have, also, the Melon and the Neal groups, on Springer creek. The Melon shipped 92 tons last year. The old winze at the Evening Star mine, Drayton creek, is to be unwatered, and, if the report of the old-time miners that the bottom of the winze is in ore is accurate, the winze will be extended and a tunnel driven from the surface to meet the extension. Some good ore has been taken from the upper workings.

TRAIL.—Three years experimentation has culminated in a satisfactory solution of the problem of the treating of the Sullivan mine ore. The ore is a compact sulphide, being an intimate mixture of zinc-blende, pyrrhotite, and galena, with 3 to 10% insoluble. A satisfactory method has been devised, however, and a plant with a capacity of 600 tons per day has been erected. The latest plan consists of treating the crushed ore on tables, thereby removing a little of the heavy galena, at one end, and most of the gangue at the other. The middling is then subjected to wet magnetic separation for the removal of the pyrrhotite and finally to preferential flotation for the separation of the galena from the blende. A 2500-ton unit is to be built at the mine at Kimberley.

HAZELTON.—B. Smith, of the American Smelting & Refining Co., visited the Sunrise mine, on Nine-Mile mountain, to plan development work that is to be done on the property, and he left Duke Harris in charge of the operations. The Delta Copper Co. is re-opening its property on Rochede Dehoule mountain, under the supervision of W. G. Norrie Loewenthal, of the Silver Standard mine. Arthur Lindquist is manager.

VICTORIA.—The Temiskaming Mines Co., of Ontario, has bonded a considerable area of ground in the vicinity of Battle lake, Vancouver Island. It is situated about two miles from the north end of the lake, and on the western side, and geographically is in about the centre of

Vancouver Island. The property under consideration by the Ontario company is an immense belt of low-grade copper ore carrying small quantities of gold and silver. The belt is said to be 600 ft. wide and to have been traced for several miles, but only a small amount of surface stripping and open cutting has been done, and at present the extent and value of the orebody is quite problematical. The Temiskaming company will start exploration work at once.

ONTARIO

CONIAGAS NEGOTIATING FOR TRETHERWEY-COBALT.

COBALT.—The deal between Coniagas company and the Tretthewey-Cobalt for the purchase of the Cobalt property of the latter is progressing. The Tretthewey joins, and could be worked in conjunction with, the Coniagas, thus eliminating dual management. The deal involves the mill as well as the mine of the Tretthewey, and if it is made the Tretthewey company will doubtless concentrate effort on its Castle property in the Gowganda district.

The Crown Reserve will mine a large tonnage of low-grade ore on a plan similar to a quarry system. It is believed that in this way a substantial revenue will be realized from deposits previously looked upon as valueless. The high quotations for silver and the increasing efficiency of workmen makes the scheme feasible. During the week of January 17, the Mining Corporation shipped 221 bars of bullion, containing 221,573.01 oz. of silver. At present silver quotations, plus about 8% exchange on New York funds, the value of the consignment is estimated at \$140 per ounce, or \$310,202. Stellite, a steel alloy in the manufacture of which cobalt plays an important part, is being used more and more in the making of high-speed tools and cutlery. This has led to a revival of interest in some of the outlying properties in which the silver content is too low for profitable mining, but where wide veins of cobalt occur.

With silver averaging \$1.30 per ounce the mine-workers of Cobalt are receiving an average of over \$5 per day. Machine-runners are paid \$4 per day plus a bonus of 25c. per shift when silver averages 80c. per ounce or over, and an additional bonus of 25c. for each 10 points above 80c. Thus, with silver at \$1.30 per ounce, the bonus amounts to \$1.50. As long as quotations for silver remain high no further labor trouble is anticipated in Cobalt.

TORONTO.—The attention of the Government is being drawn to flagrant misrepresentations in connection with the sale of stock in mining companies. The Carveth Gold Mines, Ltd., advertising its stock in Montreal newspapers, stated that its claims were situated "in the very heart of the gold-yielding district of the Porcupine Division which is producing today the major portion of the world's gold". So far from being in the heart of the Porcupine division the Carveth properties are on the extreme edge of it about 20 miles from the gold-producing centre. The authorities are being asked to take prompt action to suppress fraudulent statements of this character.

ARIZONA

Douglas.—During the past year the Calumet & Arizona Mining Co.'s production of copper totaled 46,150,000 lb., 'made' at a cost of 13c. per pound. This figure is, of course, exclusive of excess profit taxes and a reserve for ore depletion, but as it stands is comparable with any others in the copper-producing industry.

A five-year record of production and costs shows the following:

	Production in pounds	Cost in cents
1919	46,450,000	13.0
1918	51,357,154	14.4
1917	62,397,017	13.0
1916	74,898,788	9.0
1915	65,268,910	7.4

During 1919, \$3 per share was paid in dividends on 642,453 shares. The company could have maintained the early rate of \$1 per share quarterly throughout the whole twelve-month, but preferred to keep in liquid condition. Net profits not only covered the dividends paid, but will finally show something left for surplus.

Kingman.—A recent cave on the 650-ft. level of the Gold Ore mine has revealed the ore-shoot which was opened on the 250-ft. level. The mine is to be re-opened.—Mill-tests, which are being run on the ore of the Diamond Joe mine at the flotation mill of the Arizona Molybdenum Co., have shown an extraction of 82%. At the Diamond Joe there are 8000 tons of ore on the dump which are said to assay 21 oz. per ton, in silver.

Mayer.—The recent strike of high-grade chalcopryrite on the 350-ft. level of the Arizona Copper & Mining Corporation's mine is causing considerable local excitement.

Ray.—The new mill of the Gila Development Co. started operations on January 2. It is estimated that 20,000 tons of gold ore has been developed. Cross-cutting to the vein at the 200-ft. level is now under way. This property is situated three miles north-east of Kelvin. J. C. Devine is in charge.

Tucson.—R. J. Monahan and associates have purchased from J. M. Pemberton the Bondurant Gold group of claims situated in the Quijotoa district 80 miles south-east of Tucson. Development by a shaft 90 ft. deep has opened ore assaying as high as \$25 per ton in gold. The ore also carries 6 to 8 oz. in silver.

The Arizona Tucson Copper Co., nine miles south of Tucson, has made its first shipment of gold, silver, and copper ore. The new vertical shaft is down 75 ft. Cross-cutting to the orebody is to be done at the 100-ft. level. Shipments are to continue to provide funds for development.

Wickenburg.—The Gragon Mining Development Co. has started its mill, which recovers \$8 per ton in gold and silver with a considerable quantity of vanadium. This property, which is situated eight miles north of Wickenburg, has been under development for the past four years and is now in condition to continue milling for some time to come.

CALIFORNIA

Hayfork.—Big Creek Mining Co. is completing arrangements for extensive work on its placers near Hayfork. Liti-

gation affecting water rights has been settled. The holdings are among the most promising in Trinity county.

Minersville.—Following extensive prospecting new capital has become interested in Humboldt Placer Mining Co. and work will start shortly on the large holdings of the corporation. Property includes water-right and lies near Stewart's fork of the Trinity river.

Nevada City.—H. T. Rudisill has purchased the Baltimore, Dewey, and Mayflower placer-claims and Montana quartz-claim from Frank A. Garbutt. The claims are in the Eureka district and for several years have been worked with good results.—The tunnel being driven under Harmony ridge by the Penn-California Mining Co. is in 1100 ft. and is expected to reach the channel within 100 ft. The rock is excessively hard and about a month was required to drive 65 ft. The tunnel is 7 by 5½ ft. The property embraces 1000 acres and includes about two miles of the channel. Arthur W. Hoge is manager.

Sierra City.—An electric power line has been built from the station near Loganville to the Cleveland mine. All mine-equipment and 20-stamp mill is to be electrically driven. Underground conditions in the Cleveland and Monarch are reported excellent. Both mines are controlled by R. G. Gillespie.

IDAHO

Coeur d'Alene.—The Bullion Mining Co. will resume operations as soon as water flows again in the creek, possibly within 30 days, according to James H. Taylor, manager. At the time of the suspension which resulted from the cold weather last December, the face of the drift had reached a point more than 3600 ft. from the portal of the tunnel and ore had been followed for 170 ft. The body is eight feet wide and contains some copper, gold, and silver.—The Tarbox Mining Co. has demonstrated the existence of large bodies of lead-silver-zinc ore in East Coeur d'Alene. These bodies are 11 to 80 ft. wide and have been opened to a depth of 1000 ft. by a shaft and winze and considerable lateral work. Convinced that he has sufficient ore-reserves, Richard Daxon now proposes to install a concentrator.—Negotiations have been closed for the transfer of the Jim Blaine group of eight lead-silver claims on Pine creek to the Jim Blaine Silver Syndicate, recently incorporated with headquarters at Spokane. The incorporators are Matt Baumgartner, John Jahde, and W. L. Niehorster, and the articles call for a capital of \$100,000.

MISSOURI

Joplin.—The American Lead & Zinc Co., one of the leading producers of the country, has resumed operations at its No. 3 mill, south-east of Cartersville, preparatory to opening up new ground that promises production for a long period. A map of the underground workings shows practically 82 acres in one hole, except for the pillars left to hold the roof.

—The Miller Mining Co., recently organized at Webb City, has begun work at the Concord mine which it leased a few days ago. The mine has been developed recently and has an excellent 300-ton mill. The plant will be put in operation as soon as the mine has been unwatered.

NEVADA

Austin.—A seam of rich gold ore from a few inches to one foot wide is being followed in a drift being driven north from the 500-ft. tunnel of the Nevada Birch Creek Mining Co. in the Birch Creek district, 12 miles south-east of Austin. The remainder of the face is reported to be in high-grade mill ore.

Cactus.—It is expected that work will be started on a good scale by the Cactus Nevada within the next few weeks. A number of sales of claims are reported to have been made in the district recently and the new owners are waiting for the Cactus Nevada to start work before attempting to finance companies.

Goodsprings.—A new deposit of platinum-bearing ore has been found in the Boss mine, according to reports received here. The ore was found below the old workings and work is proceeding to determine its extent.

Simon District.—A cross-cut has been started south-west from the north-west drift on the 400-ft. level of the Simon Silver Lead to open the main vein beyond a fault with an estimated throw of 300 ft. This is the main fault; 500 ft. south-east of this there is another with a north-east throw beyond which drifts have been driven on the 300 and 400-ft. levels. Between these faults is the main developed part of the vein. Beyond the south-east fault the vein was found narrower and rich. The shaft, which is being sunk to 600 ft., has reached the 450-ft. point.

UTAH

Park City.—Shipments from this district for the week ending January 17 totaled 2198 tons, as compared with 2292 tons for the previous week. A noticeable increase in the output of zinc ore from the Judge M. & S. Co.'s mine was made during the current week. Mines and tonnages are as follows: Ontario, 652 tons; Silver King Coalition, 551 tons; Judge M. & S., 407 tons; Judge M. & S. (zinc ore), 261 tons; Daly-West, 219 tons; Daly Mining, 53 tons; and Naildriver, 55 tons.

Development of the upper levels and virgin territory in the Daly-West has resulted in opening up promising ground in this famous old producer. Some of the unprospected areas embrace veins and contacts covering the entire length of the property, which is approximately 3100 ft. on the strike of the veins. Several drifts and raises have been started into this new territory, three of which have developed ore of high grade. One strike in particular, made during the early part of January, shows an average value of \$125 per ton. About ten tons of this material is being mined per day. A great many permanent improvements to lessen operating costs have been completed, among them being the Daly-West shaft, which now has a direct connection with the Judge M. & S. main operating tunnel, through which the Daly-West milling-ores can be delivered to the Judge concentrating-mill for treatment.

ONTARIO

During 1919 the Coniagias company milled 71,743 tons of ore and 20,683 tons of old sand, at a total cost, including royalties, taxes, and head-office expenses, of \$398,716. Deducting \$1 per ton for re-grinding and treatment charges on the old sand, the total cost of treating the ore was \$378,033. The following table gives the per-ton cost of various items:

Mining	\$1.613
Milling	1.479
Marketing ore and concentrate	0.977
Office and supervision	0.504
Taxes and royalties	0.586
Sundry expenses	0.111

Total \$5.270

Personal

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Ben. B. Thayer is on his way to Chile.

Clifford G. Dennis has returned from an inspection of mines at Austin, Nevada.

James W. Neill has returned from Mill City, Nevada, and has gone to Vancouver, B. C.

A. V. Thorns, of Tacotna, Alaska, is in San Francisco, this being his first journey 'outside' for 17 years.

Robert M. Keeney, consulting engineer to the York Ferro-Alloys Co., will be at York, Pennsylvania, for several weeks.

E. M. Hamilton is going to El Oro, Mexico, to advise in regard to the milling practice of the Mexico Mines of El Oro.

Eben E. Olcott, of New York, is in San Francisco, to meet his son, Lieutenant Charles Olcott, on his return from Siberia.

Forbes Rickard has been appointed consulting engineer to the London Mining & Milling Co., operating at Alma, Colorado.

Herbert Stone has returned to San Francisco from Homestead, Oregon, where he was in charge of the development of the Copper Dyke mine for the past two years.

E. H. Brownell, vice-president and general manager of the A. S. & R. Co., has been visiting that company's smelters in Utah while on his way from the Pacific Coast to New York.

W. J. Loring and his son, **Edward A. Loring**, were at the Plymouth Consolidated at Plymouth, California, recently. E. A. Loring proceeded on his return trip to London, while W. J. Loring will continue on one of his periodical visits to various Mother Lode mines under his supervision.

Obituary

Robert Hollister Chapman died of pneumonia at Washington on January 11, at the age of 52. He was born at Hartford, Connecticut, and spent most of his life as topographical surveyor on the staff of the U. S. Geological Survey. His skill attracted the attention of the Canadian government, to which he was lent in 1909 for the purpose of introducing American methods in the work of the Canadian Geological Survey. He was an enthusiastic mountaineer, and during the Taft administration he was in charge of the Glacier National Park, in Montana. During the War he served with the Engineers Reserve, obtaining the rank of major and becoming assistant to General Theodore Bingham in producing airplane maps and planning the defenses of New York. He was beloved by a large circle of friends and accomplished more than his share of useful work in the world.

Richard Cockburn MacLaurin, president of the Massachusetts Institute of Technology since 1909, died on January 15 of pneumonia at his home in Cambridge. During his 11 years as president, and owing largely to his influence, the Institute has received handsome endowments, which have enabled it to increase its facilities to an unprecedented extent. He was born at Lindean, Scotland, on June 5, 1870. In 1896 and 1897 he received the degrees of Bachelor of Arts and Master of Arts from St. John's College, University of Cambridge. For the next ten years he was professor of mathematics. For two years he served as dean of the law school in the University of New Zealand. In 1907 he was professor of mathematical physics at Columbia University, and had just been appointed head of the physics department, when he resigned to become president of Technology and began a new career of national usefulness.

THE METAL MARKET

METAL PRICES

San Francisco January 31

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	11.00

Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

January 30.—Copper is quiet and steady. Lead is quiet and firm. Zinc is inactive and easy.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

The important position of gold in the world's finances is readily seen from a study of the gold reserves of various countries and the part these reserves have played during the War. To supply credit and to meet the existing demand for more currency, nations placed their main reliance upon the issuance of bank notes, and similar obligations. This artificial increase of the money supply, and the consequent depreciation of the currency of great nations. In fact it has been due to this condition more than to the law of supply and demand or decreased production, that we are now experiencing the "high cost of living".

The following tables, compiled by the Bureau of Mines from the Statist, illustrate in compact form what has occurred in recent years to the currency of various nations:

Table I—Gold Holdings of Various Great Banks of the World

	Prior to War	1919	Increase or decrease
England	\$125,197,000	\$557,666,000	+ \$432,469,000
France	297,895,000	1,083,716,000	+ 785,821,000
Germany	304,527,000	260,469,000	- 48,058,000
Austria-Hungary	431,276,000	55,789,000	- 375,487,000
Italy	213,840,000	150,579,000	- 63,261,000
Japan	102,298,000	306,580,000	+ 204,282,000
United States	65,654,000	256,030,000	+ 190,376,000
Other countries	1,831,126,000	2,119,843,000	+ 288,717,000

Table II—Notes in Circulation

	Prior to War	1919	Increase or decrease
England	\$1,121,101,000	\$2,051,605,000	+ \$1,930,504,000
France	1,119,273,000	7,153,808,000	+ 6,034,535,000
Germany	159,450,000	7,237,526,000	+ 7,078,076,000
Austria-Hungary	131,276,000	9,153,650,000	+ 8,992,374,000
Italy	309,923,000	2,017,183,000	+ 1,707,260,000
Japan	151,894,000	199,710,000	+ 47,816,000
Holland	155,728,000	111,389,000	- 44,339,000
United States	2,431,787,000	3,569,461,000	+ 1,137,674,000

Table I indicates that of the principal contributors in the Great War, the Central Powers suffered the greatest decrease in gold holdings, while among the Allies but one nation, Italy, experienced a decrease. Table II shows, however, that she has not much significance, but when studied in relation to Table II, which is a tabulation of the increase in paper money in circulation for an equal period of time, some important results appear. Thus England, against an increase of \$967,500,000 in gold holdings is credited with a note expansion of nearly two billion dollars. France against an increase of \$288,717,000 in gold holdings shows an increase of \$6,034,535,000 in paper currency. The ratio is greater in the case of Germany and Austria-Hungary, the former country, against a decrease of \$6,034,535,000 in gold reserves, indicates an increase of \$6,778,118,000 in notes, while the figures are even more startling for Austria-Hungary.

Foreign exchange quotations on January 27 are as follows:

Sterling, dollars: Cable	3.58
Demand	3.57
Francs, cents: Cable	7.92
Demand	7.91
Lire, cents: Demand	6.81
Marks, cents: Demand	1.25

Eastern Metal Market

New York, January 21.

The markets are generally quiet but prices are in most cases steady. Speculation abroad is not as erratic and this has had its effect here. Domestic demand is also less.

Demand for copper has subsided and the market is easier. Tin was heavily bought again last week but prices are uncertain.

The heavy demand for lead has slackened but prices continue high and firm.

The zinc market is quiet but steady.

Antimony is in heavier demand and higher.

IRON AND STEEL

Car-shortage is cited as one of the more important factors hindering the steel industry, to say nothing of low labor-output per man. The Steel Corporation still maintains its policy of holding to the March price schedule but many mills have gone beyond these figures. The view is expressed that the fixed prices obtaining during the War, \$11 to \$12 per ton higher, and then regarded as reasonable, are surely justifiable now because of generally higher manufacturing costs. Activity in pig-iron the last week has overshadowed that in steel.

There are indications that railroad demands will have to take their place alongside the general demand. The first definite locomotive inquiries for this year include 100 for the Union Pacific, 45 for the Great Northern, and 40 for the Missouri, Kansas & Texas. The fabricated steel trade is very promising with projects of a huge total awaiting decisions in the face of high labor and material-costs. Among the spectacular purchases of the week was the order for 87,000,000 nuts by the Ford Motor Co. distributed among a number of makers.

COPPER

Demand is light and the market is very dull. This is regarded as only natural following the heavy buying for both domestic and foreign account which prevailed a few weeks ago. Copper buying goes in waves and this is the fourth in the last 13 or 14 months. On the last movement a price as high as 23 to 23.50c. was realized. Present buying is confined to moderate amounts, depending on the needs of the consumers. Speculative dealings have been checked as far as possible for some weeks. Electrolytic copper for early delivery is quoted at about 19 to 19.25c., New York, with Lake at about 19.25 to 19.50c. The larger producers are asking 19.25c., New York, for electrolytic and 19.50c. for Lake.

TIN

The London situation continues to be a dominant factor in the market and prices have been erratic. At each recession there, buying here has been heavy. About the middle of last week a better demand appeared after a period of dullness. This resulted in the purchase of 700 to 800 tons in an extremely competitive market. Tin-plate makers were the heaviest buyers. On Monday, January 19, the market was again quiet, buyers not being attracted because of the higher asking-price of sellers who offered spot Straits at 64.25c. and futures at 64.50c. Yesterday spot Straits ruled at 64c., New York, with Banca at 63.50c. and a fair inquiry was reported. The London market is rapidly approaching the record price of £399 per ton for spot Straits, established in 1917. Yesterday this position and brand was quoted at £386 per ton. Arrivals thus far this month have been 2280 tons, of which 415 tons is credited to Pacific ports. The quantity afloat is reported as being 6330 tons.

LEAD

It is possible that the advance has been checked and if so it will be salutary. The heavy demand which has persisted recently has subsided to a marked degree. Prices are firm with wholesale lots for early delivery quoted at 8.75c., New York, or 8.50c., St. Louis. Spot lead is a little easier but is still quoted at 8.37½ to 9c., New York. Last Thursday the American Smelting & Refining Co. again advanced its quotations to 8.50c., or 8.25c., St. Louis, to more nearly keep abreast with the outside market. A steady market is expected for some time, with an ultimate recession in values as heavier supplies begin to be felt, unless the situation in Mexico, Spain, and Australia should upset conditions and cause foreign demand to seek satisfaction in the American market.

ZINC

This market is quieter than in some weeks. A better demand is reported from galvanizers who seem interested in nearby delivery but foreign inquiry has subsided to a considerable extent. It has not lost interest, however, and as soon as exchange is more stable it will undoubtedly revive. Urgent demands are evidently covered. Strikes in some Western smelters are an unfavorable factor at present and further labor troubles are not unlikely. Prime Western for early delivery is quoted at 9.30c., St. Louis, or 9.65c., New York, with some producers asking as high as 9.37½c., St. Louis. The course of the London market continues to exert an influence on values here but not to so marked an extent as in the last few weeks.

ANTIMONY

The market is much stronger. Wholesale lots for early delivery are quoted at 10.75 to 11c., New York, duty paid.

ALUMINUM

Wholesale lots of virgin metal, 98 to 99% pure, are quoted at 31.50 to 32.50c., New York, for early delivery.

ORES

Tungsten: A rumor is afloat that certain senators have told friends in the tungsten industry that a tariff will be passed in the near future, covering this product. Just what it will be is not known, of course. In the meantime the market is very dull and prices are nominal at \$6.50 to \$15 per unit in 60% concentrates. Open quotations on ferro-tungsten are not heard of, but the selling price is probably from \$1 to \$1.15 per pound of contained metal.

Molybdenum: The market is inactive and quotations are nominal at 75c. per pound of MoS₃ in regular concentrates.

Manganese: The market is strong and advancing and the ore is scarce. Makers of ferro-manganese are reported willing to pay as high as 75 to 80c. per unit for high-grade ore. This contrasts with 50 to 55c. about six to eight weeks ago.

Manganese-Iron Alloys: Domestic producers of ferro-manganese have temporarily withdrawn from the market for last-half delivery, due largely to uncertainty regarding ore-supplies and cost of production. They are out of the market for the first half and there is only a limited quantity available for the position at around \$150, delivered. The Anaconda Copper Mining Co. will soon start producing electric alloy and two or three more blast-furnaces will be producing soon. At least 500 tons of British alloy is available for delivery after March at \$150, seaboard, and perhaps more can be obtained. Spot alloy is held at \$150 to \$180, delivered, and some small sales are reported. Spiegeleisen is strong at a minimum of \$47, furnace, with one maker asking \$55. Sales of several hundred tons for domestic account are reported.

Book Reviews

Further Incidents in the Life of a Mining Engineer. By E. T. McCarthy. 400 pp. Frontispiece. George Routledge & Sons, London. For sale by 'Mining and Scientific Press'. Price, \$3.50.

This is a sequel to the 'Incidents in the Life of a Mining Engineer', reviewed in our issue of October 26, 1918. It appears—and we are not surprised—that the success of the first volume induced the publishers to beg the author to continue the story of his life and adventures, which in the first volume ended in mid-career with his return from South Africa in 1898. The proceeds of sale from the first volume went directly to the benefit of the St. Dunstan's Hostel for the Blind, and \$4000 was raised thereby. The profit accruing from this volume will be used for the same beneficent purpose. This sequel, like its predecessor, is an unadorned, straightforward story of an extraordinarily adventurous career in the remote places of the earth. Mr. McCarthy has faced death in more guises than any man we have known and he tells us all about it without frill or rhetoric of any kind. The style of the book is unpretentious to a fault; the spelling of names is wrong often; he does not trouble to round his descriptions with book learning; he omits the names of places and people where the reader's curiosity asks for them; dates are missing; and he fails to give maps, which are so helpful in a book of travel. These are the faults. They are those of a letter writer; indeed the story he tells is such as a man would write home to a friend; it is not literary, but its sincerity more than redeems its obvious defects. The matter is so good that we regret the manner is not pitched higher, but others may find this no blemish, and, for ourselves, we wish devoutly that writers of greater skill had as much real information and lively incident to record as our friend in London, a mining engineer in the first rank of the profession and a man whose true character is delightfully disclosed in the ingenuous recital of the queer things that happened to him in strange corners of the map. The first seven chapters cover his life as manager of a gold-copper mine in Chiapas, Mexico, near the Guatemalan border. These chapters alone would make a book, if treated in the customary expansive way. Then Swaziland, in South Africa, holds the reader for nine chapters. He describes how he organized and led the exodus of a mining community from Swaziland to Delagoa Bay on the eve of the Boer war. He was manager of the Pigg's Peak mine; with 20 wagons and 400 oxen, besides 45 horses, he conveyed 74 white people, including women and children, besides 200 natives, to the place of safety. The trek occupied four weeks, although the distance was only 200 miles. They arrived safely, and just in time to escape the ravages of warfare. The Far East calls, and the author tells us about his experiences in the Malay States, Borneo, and Korea. He shows an understanding sympathy with the unsophisticated natives and recites many illuminating stories about them. Twenty chapters are devoted to this part of his life. Then come travel and professional work in Siberia, where he was consulting engineer to several important copper enterprises. He was in contact with Bolshevism and its discomforts. Mexico, Siam, Borneo, Canada are the scenes of the last reminiscences. In the latter part of the book he condemns unsparsingly the humbug that misrepresented the employment of Chinese coolies in the Transvaal. He crossed the straits of Tsushima during the famous naval battle between the Russians and the Japanese. The book ends with a touching reference to the gentle lady, his wife, to whom it is dedicated. All that he writes is genuine, his style is that of 'l'homme même', which is Buffon's definition of the real thing. We commend the book heartily to the profession; it is a bulky book, chuck-full

of interest. Buy it, for your own benefit and to help the Hostel for the Blind. T. A. R.

Millions From Waste. By Frederick A. Talbot. Pp. 308. J. B. Lippincott Co., Philadelphia. For sale by 'Mining and Scientific Press'. Price, \$5.

As a result of the War, the scrap-heap has come into its own. In fact, the expression 'thrown upon the scrap-heap' no longer has its old significance, since all it probably indicates is that the article in question has simply been placed in a convenient place for storage until it can be worked over into some other useful form. The present volume deals with the reclamation of waste of all kinds, from scrap-iron to fish-offal. Although it is written from the British standpoint, the solutions that are given of the various problems are as applicable to American conditions. In general, each chapter considers some particular kind of waste product, discussing both the extent of such waste and the processes that have been developed for utilizing these products. Wastes from the kitchen, the slaughter-house, the fishing industry, the ash-can, the sewer, the metal industry, and many other branches are discussed. The treatment is popular enough to be interesting, but not so popular as to fail of being informative.

Petroleum Refining. By Andrew Campbell. Pp. 282, ill. (together with about 25 large inserts), index. Charles Griffin & Co., Ltd., London. For sale by 'Mining and Scientific Press'. Price, \$8.50.

Although petroleum refining is one of the more important of the world's industries, this is the first treatise to be published devoted exclusively to its technology. The book covers the same general lines as the second volume of Bacon and Hamor's 'American Petroleum Industry', although the treatment is not so full as in the latter book, and the present volume is based upon English and Colonial rather than American practice. The latter difference, however, is more in details such as the standard size of tanks rather than in actual processes. The first chapter, which comprises nearly one-third of the book, is devoted to methods of examination and testing of crude oil. Then follows a review of the principal departments and processes in the refinery, including methods of distribution. A chapter is devoted to specifications for tanks, stills, and other refinery apparatus. The appendix contains a bibliography of references relating to petroleum, particularly refining.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

COMMERCIAL PARAGRAPHS

Hugh L. Siegel, formerly general sales manager for the Ford Roofing Products Co., is now with Walter A. Zehucker Supply Co., as assistant to the president.

Arthur Elliot Allen has been appointed district manager at New York for the Westinghouse Electric & Manufacturing Co. to succeed Edward D. Kilburn, who has been elected vice-president and general manager of the Westinghouse Electric International Co.

The Monel Metal Products Corp. announces the appointment of W. M. Corse as general manager. Mr. Corse was formerly general manager of the Titanium Bronze Co., and is now technical superintendent of the Ohio Brass Co. He took up his new duties on January 1.

Bulletin 1818 from the Allis-Chalmers Manufacturing Co. describes equipment for use in the converting department of copper smelters. Besides sundry types of converters, matte ladles, ingot-casting machines, cranes, and lining equipment are depicted and their best features pointed out.

Bulletin No. 60 just issued by the Mine and Smelter Supply Co. announces a change of policy in that the company will hereafter market belting, hose, and packing under its own private 'Masco' brand. The bulletin outlines the products which are to be included in the new line.

A new bulletin, No. 101, entitled 'DFC Fire Clay Products', deals with annealing-cups, cupels, crucibles, muffles, scorifiers, and special dishes and tile in an interesting and comprehensive manner. It can be had by writing to the Denver Fire Clay Co., Box 1107, Denver, Colorado.

A new bulletin entitled 'Lane Electric Cranes', has just been issued by N. B. Payne & Co., 25 Church St., New York City, agents for the Lane Manufacturing Co. of Montpelier, Vermont. The bulletin fully illustrates and describes several styles of cranes in which steel girders or heavy timbers of long-leaf yellow pine are used.

Goodwin M. Trent, manufacturing engineer, Sharon building, has issued Bulletin No. 1 describing the construction and advantages of sundry cyaniding equipment including the Trent agitator, Trent thickener, Trent replacer, zinc boxes, and slime pumps. The principles involved in the operation of the 'Universal' cyaniding machine are detailed.

A recent bulletin from the Pelton Water Wheel Co. outlines the characteristics of the various Pelton centrifugal pumps. In addition many practical data are given regarding methods of driving; arrangement of pumps in combination; installation and operation; type-selection and other valuable engineering details. Bulletin No. 10 is well worth having.

Although the Thermit process has been used since 1903 for making marine repairs and has a great many successful welds of this nature to its credit, the process till now was never officially approved by the American Bureau of Shipping, and most of the repairs were made on vessels not classed by them. It is due entirely to the unbroken record

of successful marine welds that the Bureau has accorded its official sanction to the process. According to a statement by the Metal & Thermit Corp., there has never been a single failure of a Thermit marine weld so far as it has been able to ascertain in all the years that the process has been used under this company's jurisdiction.

Glenville A. Collins, recently North-West manager for the Wellman-Seaver-Morgan Co., has resumed consulting practice as mining, civil, and mechanical engineer with offices at 1316-18 L. C. Smith building, Seattle, and branches at Portland, Tokyo, and Shanghai. Collins-Ferguson Co. at the same address will conduct domestic and foreign trade in machinery and metal products, and will undertake the construction of plants under operating guarantees.

The Southwestern Engineering Co. has issued Catalogue 'B', giving in a very attractive way the features of the 'K and K' flotation machine. The list of companies that use the machine includes some in Alaska, Chile, and Japan, in addition to some 60 others in every important mining district in North America. The machine is described in detail, and directions given for setting up. The last half of the pamphlet is given over to reports of ore-tests made by the company in its own plant at Culver City, California. Flow-sheets based on the results are shown. Commercial plants were actually constructed from designs determined, so that the material presented is of more than theoretic value. The catalogue is an extremely neat little book.

The Chicago Pneumatic Tool Co. announces the appointment of E. A. Woodworth as special railroad representative attached to the staff of the manager of Western railroad sales, with headquarters at Fisher building, Chicago. Mr. Woodworth has been for several years secretary of the Committee on Standards, United States Railroad Administration. Prior to his engagement in the Government service he was associated with the Oxweld Railroad Service Co. and O'Malley Barre Valve Co. C. E. Laverenz who has been given a similar appointment was for several years an inspector in the Ordnance Department of the United States Navy and previously held positions with the Chicago and Northwestern and Illinois Central railroads.

Allis-Chalmers Manufacturing Co. has issued Bulletin 1532-A descriptive of the Diesel-type oil-engine which it builds. Crude or residual oils will only partly vaporize under the most favorable conditions obtainable in an engine and usually contain combustible matter that will not vaporize under any condition. The Diesel engine in overcoming this difficulty represents the highest development of the internal combustion engine. The Allis-Chalmers oil-engine combines all the economical advantages of the Diesel system, together with special constructive features essential for reliability in service. The engine is of the four-stroke cycle horizontal type with an open fuel nozzle and a low pressure starting system. These features simplify the design and overcome the chief objections of inaccessibility, uncertain piston lubrication and the clogging of the fuel nozzle, to which the older types were subject.

THE Canadian Mining Institute will meet in annual convention at Toronto on March 8 and the two following days. Mr. C. W. Knight, of the Bureau of Mines, is secretary to the local committee on arrangements. The annual meetings of this Institute are most successful affairs. Usually they are attended by a delegation from the southern side of the unfortified line that divides the American and Canadian peoples.

DURING the War the Bedford McNeill code was not permitted to be used, presumably because it could be employed effectively in evading censorship. This compliment worked to the injury of Mrs. McNeill, who now owns the copyright of the code. We are glad to state that it has been released from any restriction as to its use and we hope therefore that mining men will again avail themselves of its unquestioned good service.

GOLD is reported to have been struck in tunneling for the Hetch-Hetchy aqueduct where it crosses the Mother Lode region, but the find has no commercial value. We are reminded of the "streams that run o'er gold mines, yet gently, calmly glide and never know the wealth that shines beneath their golden tide". This was addressed by the poet to a 'Mary', whose character was symbolized thereby. Perhaps the City Engineer can find a similar maiden in the foothills that still glow with Bret Harte's romance; if not, he can use California herself for a poetic apostrophe.

UPON another page we publish the text of a resolution endorsing and pledging support to Mr. Hoover for President, passed by the Joint Council of Engineering Societies of San Francisco at a recent meeting of that representative body. A copy of this resolution has been forwarded to engineering organizations all over the United States. Needless to say, among other desirable results, the election of Mr. Hoover to the Presidency would do more to improve the status of the profession than a hundred years of conversation. Let our slogan be 'Up with the Engineers; Hoover for President'.

DIVERSE schemes of treatment, in which froth-flotation may play a part to advantage, are illustrated in the experimental work being done on the ore of the Sullivan mine in British Columbia. The ore consists of an intimate mixture of zinc-blende, pyrrhotite, and galena with a small amount of insoluble. The earlier method proposed to oxidize the pyrrhotite by a light roast, regu-

lated so as to leave the other sulphides unaltered; then to separate the galena and blende by means of preferential flotation. The more recent plan, which has been successfully carried out on a working scale, includes the wet concentration of the crushed ore so as to give a finished lead-concentrate, a middling, and a tailing to be discarded. The remaining pyrrhotite is removed from the middling by a magnetic process, after which the finished lead and zinc products are obtained by preferential flotation.

SIX weeks after the return of the striking coal miners to their work, the current rate of production is considerably in excess of that recorded during the corresponding period of the past three years. Distribution, however, is not yet normal, on account of the complete demoralization of coal movement by the railroads from November 1 to December 15. Readjustment of traffic is necessarily slow, and the difficulty is emphasized by the cold weather in the Central States. As far as actual mining operations are concerned, neither strikes nor labor-shortage is limiting production except in isolated instances, where it is due to purely local causes.

IN this issue we publish the second part of the article on the 'Elements of Smelting-Plant Design', by Mr. Oliver E. Jager. We believe that it will fulfill its purpose, which, as the author has said, is to help the younger members of the metallurgical profession to an understanding of the rationale of such work. It may also assist some of the older practitioners to analyze their own methods of procedure. Mr. Jager, at the present time, is with the British America Nickel Corporation in Ontario; he is a graduate of the Ballarat School of Mines in Australia, and formerly was on the staff of the Anaconda and Cerro de Paseo companies.

OWING to the slow economic recovery of Europe and the consequent lack of food supplies, the American Relief Association has devised a means of assisting the destitute without the direct shipment of food or the transmittal of money from the United States. Instead, warehouses to carry stocks of staple foodstuffs have been established in the European cities where distress is particularly acute. Next, the Relief Administration has arranged for the sale of orders, or food-drafts, on the warehouses; these can be sent to friends or relatives in Europe. The charge for such food-drafts will cover the

factory-cost of the food plus a reasonable margin to meet the expense of transportation and insurance. Any profit will be turned into the European Children's Fund. We give publicity to these facts because many of our readers in the mining districts will know men who are anxious to help their relatives in Europe. These should be told about the arrangement devised by Mr. Hoover for the purpose of helping the destitute without the many delays and deductions inseparable from the sending of anything to Europe at this time, not to mention the troubles arising from a fluctuating exchange. Write for particulars to the American Relief Administration at 115 Broadway, New York.

SALES of copper so far this year have not been maintained at the rate recorded during the closing weeks of 1919. During the first 20 days of January the four principal selling agencies and the Copper Export Association disposed of 170 million pounds of metal for foreign and domestic consumption. It is estimated that since the first week in November not less than 700 million pounds has been marketed, this figure representing the biggest business ever done in three months by the producers of copper in this country. Of the total, 200 million pounds went to Europe through the Copper Export Association. These sales have gone a long way to relieve the burden of unsold metal that has depressed our copper industry since the Armistice. The American Smelting & Refining Company, which at one time was embarrassed by its heavy stocks, has sold about 350 million pounds during the past three months. In this connection, the published figures of the copper sold by the Kennecott Corporation are interesting. In the first quarter of 1919 that company sold only 2,601,000 pounds; in the second, 9,044,000 pounds; in the third, 8,696,000; and in the fourth, 20,355,000 pounds. It is stated that since the close of the last quarter, the Kennecott Corporation has got rid of the remainder of its 1919 production, including 55 million pounds that had been carried as a surplus during the early summer.

CONTEMPT proceedings for alleged disregard of court injunctions have been brought before the U. S. District Court of Montana against the Butte & Superior Mining Company by the Minerals Separation company. Judge Bourquin has issued an order to show cause why the Butte & Superior company should not be punished for contempt. The hearing is set for February 10. It appears that the plaintiffs base their petition on the accounting filed recently by the defendants. In December 1918, the defendant company was enjoined from any use of oil in quantities of $\frac{1}{2}$ of 1% or less on the ore. Infringement was admitted for four months early in 1919. After the Supreme Court's mandate and the subsequent decree of the District Court, adjudging 1% of the oil as the limit under the specifications of the patent, another injunction was granted restraining the Butte & Superior company from the use of quantities of oil "equal to any fraction of 1%". The allegation now made by Minerals Separation is that the defendants infringed during the

existence of the second injunction, this allegation being based on facts disclosed in the course of the accounting. They claim that the amount of oil used was 18,6281 pounds per ton of flotation heading, or less than 1% on the ore treated. Hence the claim that the defendants made large profits by disobeying the injunction from the first of February to the end of May 1919. We look forward to the hearing of this new phase of the litigation.

LONDON is recognizing that gold is now a commodity rather than a measure of value, although still used as a reserve against notes. The altered status of the noble metal is emphasized by the fluctuation in its price as bullion, the highest recorded being 111 shillings per fine ounce, as against the 'normal' of 77 $\frac{3}{4}$ shillings, the difference indicating a 'premium' of 42%. This, it is recognized frankly, is due mainly to the adverse trade balance between Great Britain and the United States. Another factor is the heavy balance due to India, which has been a keen buyer of gold through the British government. Samuel Montagu & Company, the well-known bullion brokers, estimate the British stock of gold at £222,614,000 as against £890,930,000 held in the United States. While the world's output of gold is decreasing, the proportion produced by the British mining regions is increasing. This is a fact well worthy of attention at Washington. As to silver, the Messrs. Montagu refer to the enormous demand in China and India. The Chinese do not like paper currency, therefore official bank-notes are at a discount and the mints have been absorbing some five million taels of silver per month. The demand from China shows no abatement. The general prosperity of India is stimulating a similar demand on the part of the Indian people. These phenomena are part of the consequences of war, more particularly the lavish issue of paper money by the belligerent countries and the decreased productiveness of their peoples by reason of the disorganization caused by the War.

The Hoover Boom

A friend writes from Washington to say: "Reports coming in of Hoover's strength in the country paralyze the politicians here." No wonder; we note that many of our exchanges are declaring themselves strongly for the man of the hour. Men of both parties are eager to enlist under his leadership. The Los Angeles 'Times' says, "Herbert Hoover is a Republican . . . He is one of the few Republicans whom President Wilson called to his aid . . . He will have been already nominated by the Republican National Convention and his campaign will be under way when the Democratic National Convention meets." The New York 'Sun' says that "the boom for Hoover is going on both sides of the political fence at about the same rate of speed". The 'New Republic' says that he is "the candidate of the constructively minded people of America . . . A few weeks ago we should have supposed the hope of Hoover to be vain. There are signs that it is not vain, that if the demand is loud enough and insistent enough the next President can

be the man best fitted to be President." We might quote other leaders of public opinion; these are symptomatic. Even the gibes of Hearst and his friend Senator Reed have only succeeded in arousing public support. The silly story about Mr. Hoover being selected as presidential candidate at a luncheon in New York at which Viscount Grey was a guest has been denied categorically by Mr. Pulitzer, one of those mentioned as having been present, yet Hearst writes one of his highschool-sophomoric editorials in order to exploit it in his usual cheap and nasty way. The suggestion that Mr. Hoover kowtows to rank, that he is imbued with British sentiment, that he has become in any way anglicized by his sojourn in London or Australia, is amusing to those who know him. If ever there was an uncompromising American, Herbert Hoover is the man. We have seen him in Western Australia, in London, and in New York; wherever one meets him, he is so obviously, not only American, but Western American, that the suggestion of chameleonic adaptation to environment is ludicrous. As the San Antonio 'Express' says: "This gentleman, whose record as chairman of the Commission for Relief in Belgium, and as chairman of the Food Committee of the Council of National Defense, and then as United States Food Administrator, is unexcelled by the war record of any other citizen of our country, was born in the town of West Branch, and the town of West Branch is in the county of Cedar, and the county of Cedar is in the State of Iowa, and the State of Iowa is in the United States of America. He was graduated from Leland Stanford Jr. University, and that excellent school is in California, and California is another State of these United States. Also, he married a Californian—after California was admitted to the American union. Also, he is a citizen of that same California. Also, he holds several honorary doctorates from universities in such places as Rhode Island and Pennsylvania, which are pretty well established as American commonwealths. He has been very highly honored, personally, by Belgium and France, too; but, as yet, no seagreen Democrat has rebuked him as a 'Belgian', and no hidebound Republican has denounced him as a 'Frenchman'." The yellow journalist who makes love to the Sinn Feiners masquerading as 100% American, and swallows hyphens as if they were oysters, does not know a real white American when he has the chance to see one. Mr. Hoover has spent much of his time abroad; of course, he has; all the leading members of the American mining profession have received calls to go to foreign countries, and they have accepted retainers to advise European, particularly British, mining companies exploiting mineral resources in every corner of the map. Are such men as Hennen Jennings, Henry Perkins, Thomas Leggett, Charles Butters, Harry Webb, Frederick Hellmann, Pope Yeatman, William Loring, Millard Shaler, and Chester Purington any less American on account of their having practised their profession under a foreign flag? Of all of them, the most refractory to any change of character, speech, or manner, the most uncompromising American, first, last, and all the time, is Herbert Hoover. He

spent much time abroad, because his skill was in demand, but he sent his sons to California to be educated. When the War began, he dropped his private interests, first to organize relief for American refugees, and then to aid the unfortunate Belgians; but as soon as the United States entered the War, he answered the call of his own country and returned to it promptly in order to place his knowledge and experience at the service of the President. How well he did his work, it is almost unnecessary to say. The Food Administration was much the most efficient and effective department of government at Washington; it won the support of every householder and the enthusiasm of every housewife. By his works, ye shall know him. His record is open to inspection. The most competent man of his generation is indeed well fitted for the biggest task that can fall upon an American. The country is sick of petty politics and the petty men that play them; it is weary of lawyers, professors, and doctrinaires; it is tired of talk; it calls for a quiet, resourceful man, strong and incorruptible, humane but forceful, self-reliant but co-operative. Herbert Hoover is the man.

The Blue Sky Law

The prevention of fraudulent issues of stocks and shares is again the subject of discussion in Congress and in State legislatures. It is customary, in such discussions, to use two terms needing definition: 'blue sky' refers to the unlimited salesmanship of crooked dealers, or 'fiscal agents', who undertake to sell anything and everything from the metals in the earth beneath to the potential nitrates in the air above. 'Wild-cats' are ventures in which the element of risk exceeds the chance of profit. 'Wild-eating' is predatory finance. The term has been borrowed by our friends on the other side of the world; it used to be said that there were no rabbits in Western Australia because the allegorical 'wild-cats', which swarmed on the goldfields, attacked them whenever they began to spread westward from South Australia. In Nevada the word 'wild-cat', like another opprobrious term, has lost much of its sinister meaning. A man will tell his friends that he is 'wild-eating' near Tonopah when he means that he is prospecting on the fringe of a productive area. As used thus, it means an inoffensive adventure in mining, but one of slight prospects. From mining the word 'wild-cat' has been applied to every kind of risky venture, until now it may be said to involve the idea of inducing others to take an excessive risk; in short, it has a touch of the nefarious.

It appears that the Governor of New York State appointed twelve men, representing the banking business of Manhattan, to enquire into the need for enacting the marketing of worthless securities. This committee, of which Mr. A. Barton Hepburn was chairman, has prepared a report, in which the idea of registering or licensing all offerings to the public, after submission of the information requisite to prove good faith, is disapproved. The same disapproval extends, naturally, to the suggestion for subjecting the persons making such statements to civil and criminal liability. The committee feels that it "can-

not afford to adopt experimental legislation of the character adopted in our Western States"; it is of the opinion that the financial centre of the country being in New York, the State must proceed cautiously, for fear of discouraging capital from embarking in new ventures. To these conservative gentlemen, it seems unwise to impose drastic regulations upon enterprise as a whole in an endeavor to exclude a medium of possible fraud. It is believed in New York that in some Western States it has been possible for crooks to obtain licenses and to use them as certificates of good behavior. The committee informed Governor Smith that the registering or licensing of securities is "unduly restrictive of legitimate enterprise", also that legislation cannot abolish ignorance or eliminate cupidity, besides uttering a number of other sapient aphorisms, which, we doubt not, were received with applause on Wall Street. Such applause will be echoed in some quarters on this side of the continent, for the irrepressible activities of the promoters of mining schemes have suffered from the discipline imposed upon them by the State Commissioner of Corporations. The effectiveness of such discipline depends largely upon the character of the official in whose hands the authority is placed. We know that Mr. H. L. Carnahan did well and honestly for the State of California, and we believe that his successor, Mr. E. C. Bellows, is doing likewise.

Mr. Bellows has just issued a statement on the subject. He asserts that "without wild-cattling the world would today be a much poorer place to live in". To him 'wild-cattling' is not a term of reproach; it connotes inventiveness, adventure, initiative. The suggestion of contempt now implicit in the term he attributes to the doings of the bold bad men that deceive orphans and widows. He is more amiable than correct; the word originated in mis-doing and owes its kindlier touch to the easy-going good-natured spirit of the West, which pardons certain forms of queer business on account of their amusing impudence or their factitious courage. Whatever his notion of the derivation of 'wild-cattling', he does not condone its unhealthy manifestations; he is out to prevent fraud and check malfeasance. By the Corporate Securities act of California, otherwise known as the Blue Sky law, it has been found practicable "to narrow the field of operations of the smooth-tongued gentry, who have been accustomed to find their profits in the credulity of the uninformed". He finds that any effort to stop fraudulent promotions is restricted by the fact that the neighboring States do not impose similar restrictions. Therefore "the wily purveyor of scraps of paper" makes use of circular letters and newspaper advertisements. Mr. Bellows finds that some newspaper publishers are without conscience in such matters and sell their advertising columns to anyone with the price. On the other hand, the average reader is inclined to believe almost anything he sees in print. The Texas oil boom has given a great opportunity to the fakery of finance. Many newspapers are willing to publish lying advertisements and thereby help in robbing their own subscribers, the very people upon whose support they must depend. It being forbidden to use the

United States mail to defraud, the piratic promoter finds it safer to use the advertising columns of the newspapers. Mr. Bellows appeals to the daily press and reminds them of their duty to the community; he says that "the remedy for the present unfortunate condition lies first in an aroused public consciousness, which shall demand better service from the paper it patronizes". We smile, remembering the many exposures of utter lack of conscience and entire absence of any sense of decency on the part of the publishers of our San Francisco papers. At Fresno and Los Angeles he may get a response. Certainly, he would from the Portland 'Oregonian' or the Spokane 'Spokesman Review'. But Hearst, De Young, and Older! It is to laugh, sardonically. Meanwhile a bill before the United States Senate is intended to protect the public from the activities of predatory financiers. Senator Kenyon of Iowa has the matter in hand. He asserts that "the conditions which exist today are outrageous and shameful. The people of the country never had so much money to spend, and they are falling victims to these lawless speculators by the thousands. There is a perfect frenzy of buying." He maintains that legitimate business is suffering from the diversion of funds to such illegitimate speculations. It is proposed that whenever an original issue of securities is offered to the public by any corporation engaged in inter-state commerce, the issuing company shall file a statement, giving specified details of information, with the nearest United States Postmaster and with the Federal Trade Commission. It is provided that any purchaser may recover twice the amount of his subscription to the stock if any "material mis-statement is made"; also that any person using the mail to transact any stock, knowing that the required statement has not been filed, or knowing it to be false, shall be fined not less than \$5000 or imprisoned not more than five years, or both. All such laws and regulations depend for their value and effectiveness upon the persons selected to interpret and impose them; they may be so interpreted as to endanger legitimate enterprise; therefore they should be subjected to careful scrutiny. We publish the text of Senator Kenyon's bill on another page. Anybody having criticisms to offer should send them to the Secretary of the American Mining Congress at Washington; he will see that they reach the Senate Committee on Interstate Commerce, to which Senator Kenyon's bill has been referred. For our part, we believe that the detective service of the Post-Office department has done the most effective work in checking the worst forms of 'wild-cattling'; and if the blue sky laws are given inter-state scope, it should be possible to stop a great deal of wrongdoing without interfering with the business of honest men. It may not be possible to prevent the depredation of the quick-witted and unscrupulous upon the gullible and greedy, for the proverb says truly that "a fool and his money are soon parted", but it is practicable and desirable to place handicaps on wrongdoing and to protect those whose personal honesty renders them suspicious of dishonesty on the part of others. Therefore we favor reasonable restrictions on mine promotion.

Public Service and Private Practice

The Editor:

Sir—With much of your editorial on this subject in the issue of January 17, I am in accord; yet there is one phase of the question, as it affects university professors, on which you did not touch, and which I believe requires thoughtful consideration. I refer to the small salaries at present being paid to professors and those of lower rank on the teaching staffs of even our greatest universities. These are generally recognized to be quite inadequate for the service rendered; indeed, in the years since the rising cost of living has become a problem to the salaried man, the salaries of professors has been the subject of much debate. Universities, however, have to do the best they can with a restricted income; endowment funds and State appropriations cannot be increased overnight; and the result is that it has become a difficult problem for the universities to attract to their teaching staffs men of the necessary calibre. Yet if our universities are to exercise to the highest degree their functions of educating and training, not only the younger men, but those of maturer years as well, and thus are to exert their proper influence upon the development of the nation, second-rate men on their teaching-staffs will not do.

The problem of the universities thus is not easy of solution; they must be able to attract men of the requisite calibre, and they have not the funds to offer salaries in competition with our industries. Of course, the generally accepted answer has always been that men devote their lives to teaching for the love of it; but this is not all. With all the love in the world for their work, men must still feed and educate their families and support them in decent conditions—not with merely bread and butter, but occasionally a little jam. If they cannot do this, they will drift into pursuits offering higher rewards. The present alarming number of resignations from the ranks of the teachers proves that when the mounting cost of the necessities of life begins to rub shoulders with their salaries, they have no recourse but to resign.

The present time therefore is not propitious for further restrictions. The problem of the universities is to make teaching more attractive—not less—so that virile and able men will be encouraged to take it up as their life's work, or, having made their choice, will be encouraged to stick to it, in order that our students may be led wisely and at last turned forth, to stand on their own feet, with the best that the nation can offer them. As you state in your editorial, men frequently accept appointments on the staffs of our universities with the un-

derstanding that they shall be allowed to practise during their vacations or other spare time; were this privilege abolished, many universities undoubtedly would lose some of their ablest men. Moreover, the question is complicated by another factor; universities are of two kinds, State and privately endowed. Although the public, that is, the taxpayers, are undoubtedly concerned in the manner in which the State universities are administered, they have no legitimate concern with the regulation of the privately endowed institutions, other than the desire of every good citizen that the country shall have adequate facilities for educating and training the coming generations. As a result of this, if our State universities were obliged to place undue restrictions on the activities of their teaching staffs, they would be at a disadvantage compared with the private universities, a disadvantage that inevitably would result in the private universities attracting the ablest men.

You will observe that I place a good deal of emphasis on expediency; yet the problem is essentially a practical one. To recall a somewhat moth-eaten dictum, it is a condition that confronts us, Mr. Editor, a condition such that our schools and universities are finding it increasingly difficult to attract and hold the best men; and these men are the very heart of a university; on their character depends the whole strength and future of our educational system.

As for the comparative merits of commercial work and journeys of observation for increasing the efficiency of teachers, an excellent debate might be staged on this point alone. I believe that both sides have valid arguments. Certainly, if universities could appropriate funds for traveling expenses and send their teachers methodically on visits to those districts or plants where they might study their specialties, it should add greatly to their breadth of vision and therefore to their ability to influence their classes wisely; on the other hand, as I cast back to my own university days, by far the best teachers that I recall were either men who had but recently left active professional work to accept teaching appointments, or else were men who were practising at the time they were teaching. When we are responsible for work, there is a certain sharpening of the perceptive faculties such as may be lacking when we are merely observers; for that reason journeys of observation may not always stimulate the teacher so well as practice in the field.

There is a possible misinterpretation of this letter that I wish to avoid. I do not believe in the socialization of industry, nor do I believe in universities or Government

bureaus conducting scientific investigations gratis for the benefit of individuals, and thus driving independent engineers and organizations from the field. I am merely defending the custom of allowing teachers, as individuals, to practise their professions co-ordinately with their teaching, if they so desire. Although at times, as you point out, they may be employed more for the prestige of their position in the university than for their own skill, yet this is balanced in other instances by the fact that many courses at universities, and even certain universities themselves, owe their reputations to the men in charge of them. A case in point is the medical schools; in all those with which I am familiar, not only the deans, but also those who hold the chairs in the different departments are physicians and surgeons actively practising, and eminent in their profession. These are not engineers; but I believe the principle to be the same.

DANIEL CROSS.

San Francisco, January 20.

Molybdenum and Molybdenum-Steel

The Editor:

Sir—In your issue of December 20, I noted an interesting article on this subject by W. E. Simpson.

In every article that attempts to set forth the valuable properties of molybdenum-steel a criticism usually follows in short order. Those in favor of molybdenum are sometimes over-optimistic and resort to superlative terms, which are barely justified, but at the same time most of the criticisms are based on ignorance of recent developments. Mr. Simpson's article is one of the best that has come to my attention. It sets forth truly the real benefits to be derived by the addition of molybdenum to steel and correctly states that it is a "valuable auxiliary".

As Mr. Simpson mentions, there are some optimists who believe that molybdenum might replace nickel. Although not quite so enthusiastic, I do know, from results secured and because this country has no extensive deposits of nickel, that molybdenum might at some time serve a strategic purpose in this connection.

Molybdenum has often been advocated for use in tool-steels. Although believing that some day its control and use for this purpose may become better appreciated, I have never considered it as a competitor of tungsten. Its value reaches into far more extensive purposes. There is one point, however, in Mr. Simpson's reference to the use of molybdenum in tool-steels that apparently is quite widespread and which I believe to be in error. It is brought out that the highly volatile nature of molybdenum causes such steels to change in chemical composition at each re-heating. The metal molybdenum itself is not volatile except at exceedingly high temperatures. Molybdenum does oxidize, however, at about 600°C. and the trioxide so formed is volatile at low temperatures.

In recent tests molybdenum has been introduced into the open-hearth bath in the early stages of melting and has remained at a constant content therein even though it was subjected for 15 hours, not only to the ordinary severe oxidation characteristic of this operation, but

also to 'oreing down' in order to decrease the carbon content of the steel. From this and other confirmatory tests, it has been proved that molybdenum has less affinity for oxygen than either iron or carbon. Although the percentage contained in tool-steels might effect a different result, it is in my opinion doubtful whether the molybdenum would appreciably oxidize and then volatilize at each re-heating, at least not in any greater proportion than the iron itself may oxidize.

The only other point in the article to which I take exception is in regard to the possible production. Mr. Simpson makes a comparison with nickel, and says, "As to supply, no molybdenite property at present known can offer, say, 50 tons per month, whereas the nickel-bearing orebodies are so large that during the War no difficulty was experienced in extracting from one shaft alone a total of 5000 tons of ore in one day." I beg to differ with him, for I have in mind one molybdenite property that is equipped to treat 1000 tons of ore per day and produce therefrom, say, 10 tons of 60% MoS₂ concentrate per day, or 300 tons of such concentrate per month.

Although possibly this is the largest single producer, there are several others, both in this country and in Canada, equipped to bring the total production to fully 500 tons of such concentrate per month, and there are sufficient other properties that could be equipped, if the need arose, to increase the tonnage considerably. I do not know the nickel content of the 5000 tons per day mined, but since a much smaller percentage of molybdenum is used in steel, as compared to nickel, I venture to say that, expressed in tons of steel ingots (leaving out the possibility of its being a competitor as far as its properties are concerned), sufficient molybdenum could easily be produced to compare with the nickel production.

My purpose is not that of criticism; my only object is to correct a common mischief. The British steel expert told Mr. Simpson. "The future of molybdenum depends on two factors, namely, assurance of supply and price;" it is indeed true that these two factors are most important as regards the development of molybdenum-steel. Unfortunately, heretofore, many small and sanguine mine-owners and producers have entered into contracts to deliver and have failed to live up to their agreements. This has led to the opinion that a reliable supply of molybdenum could not be depended upon, and has offered a serious drawback to progress. My only purpose then is to state that when demand does arise there are responsible concerns now able to assure an ample supply.

The matter of price is of almost equal importance to supply, but further recent and proved improvements, as, for instance, the use of calcium molybdate in the place of 'ferro' as an addition-agent to any steel-bath, are such that molybdenum may be offered at a figure that cannot fail to demand recognition. I fully agree with Mr. Simpson that molybdenum will shortly fill an important place in the ever-increasing alloy-steel industry.

ON PRICHARD CREEK

THE DREDGE

The Bunker Hill Enterprise—IV

The Old Diggings and Modern Dredging Operations

By T. A. RICKARD

On September 16 last, Mr. Stanly Easton, the manager of the Bunker Hill mine, took me in his Franklin car to Murray, so that I might see something of the old diggings and also get an idea of the upper Coeur d'Alene country, the scene of many events of romantic and industrial importance. It was the day before the opening of the season for duck-shooting, and my host was being

importuned to join other sportsmen, who reported that the lakes were black with ducks. I realized that he was most unselfish in giving me his company when he might have been doing something so much better. "Get the limit in ten minutes!" was wafted on the wind as our car throbbed into propulsive motion.

The road fringing the south fork of the Coeur d'Alene

PRICHARD CREEK; MURRAY IN THE DISTANCE; DREDGE TAILING IN FOREGROUND AND THE DREDGE BEYOND THE BEND OF THE CREEK

river was excellent and the morning was fine. The water in the river was clear, but that was an ominous sign, for it indicated the idleness of the concentrating mills upstream on account of the strike, which had caused the mines to be shut-down for two months. The bed of the stream is covered with tailing, which in places has accumulated to a level above that of the road. The question arises, will this discard from the mills be re-treated some day? The answer, in part, is that the tailing at this point has been sized by the stream and the rich slime has been separated, leaving a granular material, or 'sand', which will have to undergo re-grinding before it can be submitted successfully to flotation or to any other final process of concentration. The slime has been washed down-stream and deposited in the flat above Pine creek, where it is now being dredged by suction and re-concentrated by flotation, as will be described in another article of this series.

We passed through Osburn, once the county seat, now preserved to fame by the fact that it has given its name to the big fault that crosses the valley at this point and makes a saddle in the range to our left, which is northeast. Osburn looks sad—more like a fault than a vein! As we proceeded up the main valley, Mr. Easton pointed out various mines visible from the road. Most of them are idle now, but in their time they yielded gold, silver, and lead. Some produced 'dry' ores, that is, silicious; others, good smelting ore. He mentioned names briefly famous in other days, such as the Alma and Nelly.

Just before reaching Osburn, we passed the Evolution mine, which is identified with the oldest surviving location in the Coeur d'Alene. It was located on April 30, 1885, by A. J. Prichard and his wife, Catherine. A ruined shaft-house and a fairly large dump can be seen. About 2000 ft. of driving and sinking was done on a vein containing a lenticular orebody in the thinly bedded Wallace formation. The ore consisted of galena spattered through a lime gangue, too poor to be profitable.

Nearing Wallace, we pass the infirmary, built at a cost of \$148,295. This mining community is rich and generous. A sum of \$35,000 has been left over from the Red Cross fund and there are few that need help in the district. The river flats here are smothered with reddish tailing, through which protrude the blackened stumps of large trees, suggesting the beautiful forest that clothed the valley when the miner first invaded the mountain solitudes. Wallace, ahead of us, looks like a miniature Pittsburgh, for the morning mist is blanketing the town and preventing the smoke of domestic industry from being dissipated in the upper air.

Before entering Wallace, which is 13 miles from Kellogg, we pass the Hercules mill, to which the ore from the mine is brought over a railroad. Wallace itself is a neat and attractive town, but it must be dark and cold in winter, because it is situated in a narrow canyon, so that at the winter solstice there cannot be much sunlight in its streets. It was a mistake to choose such a site for a town, when ampler space was available not far off; but the first settlers, we may presume, either did not

expect a large settlement or pitched their tents on a summer day when the shadows were short. The broad streets are asphalted. What a difference well-paved streets and alleys make to these mining towns, as compared with the old days when the traffic passed over the natural surface and the heavy ore-wagons made holes that became filled with mud in winter and with dust in summer.

We called upon James F. McCarthy, the manager of the Hecla mine and a man representing the best traditions of the mining profession. We talked about Herbert Hoover, for it was the day of the dinner given in his honor, in New York, by the American Institute of Mining and Metallurgical Engineers. We agreed that an American with such international experience was rare, and should be retained in the national service. We also talked a little about the strike, which had closed down the Hecla, although it had not affected the Bunker Hill, but I knew that if all the managers were as enlightened and humane as Mr. McCarthy labor troubles would be infrequent.

Leaving Wallace, we turned up Nine-mile canyon, passing the Northern Pacific railroad station, and then followed the branch line that serves the Interstate-Calahan, Tamarack, and Success mines. The tailing in the creek here is black, on account of the Prichard slate in the mill-ore, indicating that we had passed out of the Rexett quartzite, which encloses the orebodies of the lower valley. Two miles beyond Wallace we noted the mill and high trestle of the California Consolidated, an old property, of which Mr. Easton had charge in 1905-07. In the early days the shallow workings produced well, but deeper exploration had proved disappointing, so he concluded that the mining had been done on the wrong side of the fault, the ore above having been found on the hanging-wall side of the fault, whereas the work below had been done on the foot-wall side. The fault was *not* post-mineral. This hypothesis led to the finding of an orebody that yielded \$185,000 in profit. "A nice little operation, but it did not last long", remarked Mr. Easton. The mill was re-modeled and superintended by Oscar Nordquist, who subsequently was engaged by Stephen Birch to take charge of the Kennecott copper mill in Alaska. We pass the branch railroad line that goes to the Sixteen to One and Ole Linn mines. A spring by the roadside provokes a contemptuous reference to "the Fords that stop to take on water" from the owner of the air-cooled Franklin car. The roadway is excellent because the slate, which is the prevailing country-rock, supplies the clay needed for binding the macadam.* We are now approaching Dobson Pass. At the summit there is a benchmark of the U. S. Geological Survey, recording the altitude as 4179 ft. The view is panoramic. Mountains stretch out like tumbled giants in a geologic sleep. The nearer hills are clothed in russet and the brush is touched with autumn gold. The pine-woods have been protected from vandalism and their serried ranks stand almost unbroken. All this part of Idaho is in the Na-

*Named after J. L. McAdam, who devised this method of road-making.

tional Forest. When, in 1906, the Government sequestered the forest-land there was a loud protest at first, but this ceased when the public was won by the wise administration of the General Land Office. To Theodore Roosevelt and to Gifford Pinchot posterity will be grateful for the protection of these forests. Here and there the workings of a mine recall man's intrusion.

"Or where half-way the mountain side was furrowed

With many a seam and scar;

Or some abandoned tunnel dimly burrowed,

A mole-hill seen so far."

A great silence broods over these mountains. Man's little noises are not heard up here. Across the line into

get found in the Coeur d'Alene. It was worth \$1500, equivalent to about 80 ounces of gold. The story goes that neither partner could trust even the temporary possession of the treasure to the other, so they agreed to hack the flat disc of soft metal with an axe, thereby spoiling its greater value as a specimen.

Near the mouth of Trail gulch are three monuments to unsuccessful dredging, and it is probable that these were partly responsible for the local scepticism as to the success of the present dredge at Murray. Two of the derelict Risdon dredges started in easy ground, but their owners had neglected to ascertain whether there was any gold in the gravel. One of the dredge-masters turned

FIG. 1. MAP SHOWING THE ROUTE AS DESCRIBED

Montana are "distant hills in purple guise athrob with soft enchantment".

The road descends from Dobson Pass into a beautiful forest of white pine, fir, and hemlock, their dark foliage forming a rich background for the tamarack's autumnal livery. To one accustomed to conifers that are ever-green, the tamarack, so like the firs in summer, offers a recurrent surprise in autumn. The early falls of snow in the Coeur d'Alene do not worry the old-timer, because he knows that winter will not come until the tamarack has shed its yellow needles.

On the other side of the Pass, the road turns at the base of the mountain, where Beaver creek and a branch railroad lead to the Ray Jefferson, supposed to be a zinc-lead mine; but the mill still waits for ore. As our destination was Murray, we took the other road, following Beaver creek to Delta, where we turned up Trail gulch, passing through Myrtle and Potosi, old mining settlements. Evidence of former industry was afforded by the abandoned workings in the shallow alluvium. Potosi gulch claims the distinction of yielding the largest nug-

farmer and today reaps a richer harvest from the gold of the cornfields. When reminiscent, this disciple of Agricola, in a double sense, asserts that the superintendent of the dredging operations used to carry the clean-up in his vest-pocket, the amalgam resembling a silver thimble. The third dredge had better luck; it furrowed the gulch for half a mile, but not always down to bedrock, and when it had to dig in the shallow ground worked by the old-timers, it gave up the fight, turned around, and sank. The hull with its shingled roof could be seen from the road, resting in a pond that gave back the blue of a perfect sky. The true character of these mining operations seems to have been appreciated locally, for I was shown the tree-stump that marked a 'hold-up', meant not to steal the gold won by dredging but to get the gold coin brought hither to pay the company's employees. That the lone bandit missed the sleigh of the paymaster and instead robbed some prospective 'investors' from Boston, does not mar the point of the story.

At the head of Trail gulch is the Jenkins mill, which treated some rich gold-quartz from the Crown Point and

other veins, suggesting the source of the gold in the placer. Then comes another divide, and on the farther side is the valley of Prichard creek, the scene of early gold mining and much besides. From the top of the ridge one can see three parallel rows of gravel looking like the back of scaly saurians from the primeval slime. Listening, we heard the rumble of the bucket-line and the rattle of the boulders discharged from the dredge that had piled these rows of tailing. Blue smoke rose lazily from the burning brush, which was being removed in order to clear the ground in front of the dredge. Beyond it, eastward and a mile farther up the valley, were the weather-beaten roofs of the town of Murray. We descended smoothly, skirting a hillside adorned with autumn's coat of many colors, to which the vine-maple contributed largely, together with the huckleberry. Even richer were the red berries of the mountain ash and the blue-black clusters of the elder, just frost-bitten enough to suit the taste of the local wine-makers, whose summer supply of mild intoxicant made from the humble dandelion is now exhausted. Who said prohibition? Poor Murray! Once the centre of feverish mining activity and thronged by a hilarious mob of youthful adventurers, it lies now, old and gray, almost exhausted of its gold and of its human life, dependent upon the operations of a single dredge and hoping that its washed-out railroad may be repaired. Even the profit derived from the boot-legging pack-trains from across the neighboring border of Montana has been denied to it by the prohibition enactment, and a community in which whiskey and champagne used to be drunk with careless freedom must now perforce solace itself with the spirit distilled from the flower of the field or the fruit of the forest.

Across the valley and above the serried ranges eastward rises a bare peak, called Granite, although in fact the rock exposed is the Revett quartzite—an example of long-distance geologic observation—not mine, but that of the fellow who named it Granite peak; mine is based on a geological map. The Revett quartzite, an important terrain in the Cœur d'Alene because it encloses so many of the richest ore deposits, is named after my friend Ben Stanley Revett, a mining engineer long recognized as a leading specialist in all forms of alluvial mining. Perhaps, to be meticulous, I ought to say that the rock formation is named after a lake on the Idaho-Montana divide south-east of Granite peak. Mr. Revett proposed to divert the water into Prichard creek in order to operate a hydraulic elevator, so his name was given to the lake. The steep sides of this lake are carved from the particular quartzite to which the name of Revett has been transferred; of all the formations in this region it is the one most resistant to erosion, therefore it constitutes the crest of many conspicuous peaks, such as Kellogg, Murray, Granite, and the ridge south of them.

Turning northward, we recognized Downey peak, surmounted by another patch of bare quartzite, on which there has been established an observatory for the fire-wardens of the Forest Service. It consists of a house, 12 ft. square, with glass sides, from which, by telephone, it

is possible to give warning of forest fires over a wide range of country.

Crossing a bridge we found ourselves in Murray. By good luck the first citizen we met was Adam Aulbach, one of the best informed of the old-timers. He was at work repairing his pipe-line in front of his Fraternity Hall, so Mr. Easton stopped the car and introduced him. He plunged forthwith into reminiscences of the time when Murray was joyous with hope, and whiskey. The accompanying photograph shows Mr. Aulbach as he rested on his shovel and talked to me. He had been one of the vigilantes in Montana in 1863 and had served under General Patrick Connor in the Civil War. As a journalist, he has edited many newspapers. In 1871 he served with Henry George when that great publicist was editor of the 'Morning Ledger' in San Francisco. At his office, later, he showed me the first issue (Vol. I, No. 1) of the 'Ledger', dated August 20, 1871. He came to Murray from Eureka, Nevada, in the fall of 1883, soon after the first discoveries of gold had been made, and established the 'Idaho Sun' in 1884. He organized the Republican party in the district and helped Phil O'Rourke to start the Democrats, so as to make things lively. On the first tickets there were two ex-convicts and two men that could neither read nor write, but they were "good fellows" all the same. Two of these went to the State legislature, one was County commissioner, and the other justice of the peace. Mr. Aulbach himself spent several sessions in the Legislature as a representative from this district, and was noted for the energetic part he took in all discussions.

Between 1885 and 1888, there were 13 stamp-mills at work, but the vein-mining proved disappointing, because at a shallow depth the ore became so base that amalgamation alone did not suffice to recover the gold. Mr. Aulbach states that 40% of the gold was lost even in treating the so-called free-milling ore, because no concentrating tables were used, except one or two humping-tables, of the type once familiar in Gilpin county, Colorado.

In 1885 Mr. Aulbach organized the vigilantes in Murray, but no hanging ensued, although the town contained plenty of 'bad' men from all over the West. They were given notice and run out of town. Besides the 'Idaho Sun', he started most of the other newspapers of the Cœur d'Alene: the 'Wardner News', the 'Mullan Tribune', the 'Burke News', and the 'Wallace Press'.

I asked him about the discovery of the Bunker Hill. He knew the locators, of course. Kellogg, who, he said, was a carpenter, a quiet man, and short-sighted, showed pieces of the outcrop to Phil O'Rourke in Dutch Jake's (Jacob Goetz) saloon in Murray, and, as O'Rourke had mined in Leadville, he recognized the lead ore. Kellogg had four pieces of galena among his samples. As to the showing of ore, Mr. Aulbach said that when he went to the lode two days after the discovery, he saw 8 to 10 inches, and 3 ft. long, of clean galena. This is probable, for by that time the locators had broken the comb of ironstone and exposed the unoxidized mineral. Con Sullivan was constable in Murray at that time. Phil O'Rourke was "a pretty smooth fellow" and "got next

to" Kellogg, who agreed to show him the discovery. Phil and Sullivan planned to go there quietly, but Flaherty (who had lost his O' apparently) started at midnight and notified others to follow—among them, Jim Wardner. However, Kellogg, O'Rourke, and Sullivan got there first, because they knew the way, and located their claims: Kellogg had not located any previously, being then tied to Cooper & Peck by the grub-stake agreement. The early development was directed by Joshua E. Clayton, a geologist well-known in the West at that time. He was killed in a stage-coach accident between Wardner and Kellogg in 1889.

At Mr. Aulbach's office I saw a copy of the 'Idaho

to take an energetic part in all movements for the public good, working for the revival of the railroad, conducting Liberty Loan drives, and keeping interest alive in the mineral resources of the Murray district, including his own extensive holdings.

Bidding Mr. Aulbach good by, we joined D. H. Ferry, the engineer in charge of the dredging enterprise. After a delightful luncheon with him and Mrs. Ferry, we visited the company's office, which is remarkable as having been the court house when Murray was the county seat of Shoshone. Later it became the headquarters of the Cœur d'Alene Mining Co., the promotion of Barry N. Hillard, who was the boss of the Democratic party in

ADAM AULBACH TELLING THE WRITER ABOUT THE OLD DAYS

'Sun' of August 12, 1884, in which I found this paragraph:

"There is not a single Chinaman in camp, and none should be permitted to enter while there is a white man to lift a pick and shovel."

In the same issue is an interview with A. J. Prichard, the discoverer of gold in this part of Idaho. The editor describes him as "a tall Kentuckian", and says: "He claims entire credit for discovering gold in this region, and allows none of his old camp-companions to share even a moiety of the honor."

As we left this cheerful chronicler of a by-gone day, Mr. Easton remarked: "On different issues that have arisen in Shoshone county, the old man has been mostly right." Mr. Aulbach is now the sole proprietor of the electric lighting and water supply of Murray, which he runs in lenient fashion, scarcely paying expenses, but looking to that future when Murray shall 'come back'. He is one of the few pioneers surviving in honorable circumstance, and despite his 73 years of action, continues

the county for many years up to 1890. Across the road is the former jail, now a storehouse for the dredging company's supplies.

The dredge was at work a mile below the town. It had been brought thither from the Klondike, where it had served as the No. 9 machine of the Yukon Gold Co. on the famous Eldorado creek. It was one of the first all-steel dredges, the only wood on board being the deck, housing, and gold-saving tables. The builders were the Yuba Construction Co., of Marysville, California, and it was equipped with Bucyrus machinery, all of which was transported 3000 miles to Dawson and there assembled in 1911. The dredge worked for five years and was then dismantled previous to shipment on barges down the Yukon river for 2000 miles to St. Michael, where it was re-loaded on a steamer that carried it 2500 miles to Seattle, whence it was transported by rail on flat cars to Murray, which at that time, but not now, was served by a railroad that terminated at Paragon, seven miles above the town. This line was a branch of the Oregon-Wash-

ington Railroad & Navigation Co.; it connected with the main line at Euaville. In December 1917, a few months after the dredge had been delivered, a freshet close to Murray itself washed out the track, which as yet has not been replaced.

The hull of the dredge is 44 ft. wide, 105 ft. long, and 8 ft. deep. It was built on a slope and launched end on (see Fig. 2) into the pond provided by an old elevator-pit, which was a remainder of an earlier and unsuccessful effort to exploit this alluvium. The failure of the hydraulic elevator was due, as often happens, to the coarseness of the gravel, the larger stones choking the 8-inch throat of the elevator and compelling a cessation of work while the pipe was taken apart. A mechanical elevator was tried on Bonanza creek, where I saw and described it in 1908. At that time I made a reference* to the fact that a similar machine had been tried by Henry Bryant on Priehard creek, Idaho, in 1900. Among the other devices tried here I may mention various small Evans elevators and the Nye tailing-pump, besides the ambitious attempt of Major R. L. Hopkins to unwater the deposit by means of an open drain, 12 miles long.

It needed the very best type of modern dredges to overcome the difficulties presented by this deposit, but this method was not adopted without the objection of reputable engineers, who insisted that the ground could not be dredged profitably, basing their opinion on the evidence obtained from drifts on bedrock. They realized the large proportion of the gold that lay in the clefts and crevices of the bedrock, but considered the bedrock too hard and its surface too uneven for dredging. Indeed, the ability of this powerful dredge to dig into the bedrock explains its success as compared with all the previous efforts to mine this gold-bearing channel. The gold is concentrated close to bedrock and in it; the buckets dig two feet into the bedrock, which consists of slate traversed by ribs of quartzite, and therefore presents greater difficulty than the mica-schist of the Yukon. There a 100-hp. motor sufficed to drive the bucket-line; here 150 hp. is required. There is no overburden; the depth of the deposit averages 30 ft.; it contains many boulders ranging from one to two feet in diameter.

The working end of the dredge consists of a series of 70 buckets that dig and deliver the gravel to the gold-saving machinery. Each bucket weighs nearly a ton when empty; it has a nominal capacity of $7\frac{1}{2}$ cubic feet, or half a ton of gravel, and makes a round trip in $3\frac{1}{2}$ minutes, but as it is neither filled completely each time nor moving uninterruptedly its working capacity falls far short of $7\frac{1}{2}$ cubic feet. Instead of a nominal 8000 cubic yards, the dredge digs and raises 5000 to 6000 yards per day; but even this is a remarkable performance. The buckets move as an endless chain on a frame, called the 'ladder', which is $73\frac{1}{2}$ ft. long and suspended from the gantry, which is a girder structure 41 ft. in height of four-post trussed design and held by cables attached to the tumbler-gantry and by girder-braces. The slope of the ladder or bucket-line is varied between

0° and 49° , as required, and at either end the bucket line passes over a tumbler, on which, of course, there is a great strain, so that it is made specially strong. The lower tumbler is a manganese steel cylinder of 39 in. diameter; the upper one is hexagonal, also of 39 in. diameter.[†] When the gravel is discharged from the buckets, as they turn over the upper tumbler, it falls into a hopper, from which it passes directly into a revolving cylindrical screen, or trommel, 6 ft. in diameter and 30 ft. long, sloping $1\frac{1}{2}$ inches per foot. This trommel when empty weighs 6 tons; it revolves nine times per minute. Here the pebbles, sand, and clay are shaken and washed vigorously, so that the fine sifts through the screen, which has apertures of $\frac{3}{8}$ in. at its upper end and $1\frac{1}{2}$ in. at its lower end. The coarse material runs out of the trommel onto a shaking screen, the function of which is to save any nuggets that may have failed to pass through the apertures of the trommel. The fine drops upon the gold-saving tables, which consist of wooden frames crossed by riffles, these being strips of wood covered with $\frac{1}{4}$ -inch iron. Here the gold is arrested, together with the iron sand. At intervals this concentrate is collected and the gold separated by amalgamation. The waste, on leaving the shaking screen, is discharged from the dredge by means of a belt-conveyor traveling over three-piece troughing-idlers.

Now let us go on board and get a nearer view of the operations. We descend by a steel gangway and find ourselves close to the bucket-line, which is rattling, groaning, and heaving as it digs into a bank 13 ft. above the surface of the water and 22 ft. below. The machine is digging into the bank with relentless power, raising the gravel from beneath the water to a height of 30 ft. overhead, where it is dumped in recurrent crashes that mingle with the steady roar of the trommel. It is a noisy performance, bespeaking the contest between mind and matter.

We saw a cedar stump uprooted with apparent ease. The buckets, we were told, dig two feet or more into the bedrock, according to the depth to which the gold has penetrated, as determined by panning. The buckets are close-connected and made of manganese-steel throughout, the lips being replaceable. During the first nine months of the year, that is, up to the time of our visit, the dredge had excavated over a million cubic yards. Running time had averaged 86%. There is a constant urge to keep the wheels turning and to ensure continuous operation; the manager does not hesitate to incur the cost of any appliances that may contribute to this result. During the first eight months of 1919, an increase of 25.8% in total yardage was made as compared with the corresponding period of 1918, together with a 14% decrease in cost, despite the higher prices of labor and supplies. This was done, in part, by diligent attention to details of operating management and avoiding delays and make-shifts, by keeping plenty of repair-parts on hand. A compressor on board furnishes air-power for

[†]The tread of the tumbler is 29 in. diam., as stated, but the diameter of the flange is 62 inches.

*M. & S. P., April 10, 1909.

FIG. 2. THE DREDGE READY TO BE LAUNCHED; NOTE THE SCREEN OF TREES ACROSS THE BOW TO CUSHION THE HULL AGAINST COLLISION WITH THE OPPOSITE SHORE.

drilling, rivetting, chipping, or grinding, when repairs are made. The dredge is equipped with a little machine-shop. An oxy-acetylene welding and cutting equipment has proved exceedingly useful; it saved its cost thirty times in the first five months, says Mr. Ferry, largely by its ability to cut manganese-steel, which no ordinary tool can do. Another time-saver has been the substitution of manganese-steel plates for ordinary steel in screens and hoppers; even the discarded manganese plates are cut by the oxy-acetylene torch and used for lining the tailing-slucies. Forged nickel-steel has been substituted for ordinary cold-rolled shafts in the ladder-rollers, which were subject to frequent breaks in cold weather. Records are kept to show the service given by the repair parts; this information includes the life, wear, fit, first cost, and cost per cubic yard of material handled.

As soon as we stepped aboard, I noticed that the hull

was low in the water, almost awash, despite the pontoons provided to increase the flotation. We were shown the new transformer-house, which is fire-proof, being made of steel plates lined with asbestos. The dredge requires 400 hp, all told, to operate the bucket-line, the winches, screens, pumps, compressor, and shop-tools. The 6600-volt current as received from the Shoshone County Power Co. is stepped down to 440 volts for use on board. Previous to the erection of lightning-arresters the power-cable was burnt during a storm, but, fortunately, the switches kicked out, so no further damage was done. The dredge is heated by steam in winter, from the middle of October to early in May. Fuel is obtained cheaply by buying the wood cut in the course of clearing the ground ahead of the dredge, this preliminary operation being done on contract. Water for the washing of the gravel is supplied by two centrifugal pumps, 8 and 10

FIG. 3. STARTING OF DREDGE ON DECEMBER 5, 1917; NOTE THE HOOD OVER THE STACKLER

inches respectively, connected directly to a 75-hp. motor. The material leaving the screen is washed with unusual thoroughness.

All the cables used, for moving and mooring, are made of crucible steel and come from Roebbing's Sons. These cables are kept well greased so as to prevent abrasion by the sheaves. The machinery is driven by belts, the hardest work being done by the belt, 22 in. wide and 42 ft. long, that transmits the main drive from the motor. The belt actuating the upper tumbler is 24 in. wide and 90 ft. long, running over an 8-ft. pulley.

While we were looking around, the bucket-line was stopped in order to permit lubrication. We saw how the lower tumbler is lubricated by means of grease fed from a cylinder provided with a screw worked by a handle, which, on being turned, forces the grease into the journal bearings. This device excludes grit. For under-water work a special hydraulic graphite grease is used. The rollers of the bucket-ladder are greased once a day. The upper part of the line needs only one-tenth the lubricant required by the under-water part. Mr. Ferry mentioned the fact that one of the young men whom we saw engaged in this work was Henry Henderson, a particularly efficient worker and the son of Robert Henderson, the discoverer of gold in the Yukon. The credit for the discovery is usually given to a squaw-man named George Carmack; but Carmack knew nothing about gold mining until he got the idea of prospecting from Bob Henderson, who had found gold and was mining on Gold Bottom, a tributary of Hunker creek, in 1896. Carmack, while hunting with three Indian companions, happened to visit Henderson's diggings, where he saw the gold and how it was won. Then, when returning to his camp on the Yukon, he did some prospecting on Bonanza creek and there, on August 17, 1896, made the discovery that started the great rush to the Klondike.*

Ascending to the pilot-house, or winch-room, where one man controls the huge mechanism of the dredge by a system of levers, we shook hands with Roy Darr, who had been winch-man for seven years on Dredge No. 2 of the Yukon Gold Co. at Dawson. The dredge-master, Isaac Hinkle, also had had experience in the North; he worked last on Gold Run.

The upper tumbler, which is hexagonal, is provided with replaceable ear-plates and tread-plates. The bull-wheels, actuating the tumbler, are 12 ft. in diameter and are keyed to the 16-in. shaft of this upper tumbler; they are geared by an 18-in. pinion to the intermediate shaft (7 in. diam.), which in turn is geared to the main-drive shaft (6 in. diam.), to which 150 hp. is transmitted by the 90-ft. belt. The bearings of all the shafting are bolted to the caps of the tumbler-gantry, so as to withstand heavy strains. All the moving parts of the machinery on the dredge are covered with wooden guards, to prevent accident.

The safety-platform over the main-drive shaft affords a good position for watching the buckets as they are

emptied over the tumbler into the hopper above the trommel. Three strong sprays of water in the hopper clean each bucket and prevent any gold from being carried back into the pond. The manganese-steel of which the liner-plates of the dump-hopper, like the tumbler and other parts, is made, gives a life three or four times that of ordinary steel.

Stepping to the rear of the upper deck, we saw that the dredge works on one spud and is stepped forward on stern lines. Here I may say that by reducing the length of each step, or forward advance of the boat, by nearly one-third, it has been found that the yardage is increased. Although the boat is moved more frequently, the digging from top to bottom is accomplished more quickly, because a smaller bite is made into the bank. This is important in tough ground containing occasional large boulders. The shorter step also facilitates the closer scraping of the bedrock and saves the dredge from many severe shocks, caused by reducing the bite on boulders tightly imbedded in clay, and on hard ribs of bedrock. The spud, by aid of which the step forward was formerly made, was a steel post that was dropped through a socket, or casing, to serve as an anchor to hold the dredge in position against the digging-thrust. As now used the spud is a plate-girder of box construction, 24 by 36 in., and 48 ft. long, of which 18 ft. is in the ground. The construction of this new spud is twice as strong as that of the one used at Dawson. It works against five pairs of double-coil ear-springs of special design fixed in the spud-keeper or socket. The metal of these springs soon crystallizes, or suffers 'fatigue', so that they last six months only. In future they will be made of vanadium-steel. The vibration, when the dredge is digging even in comparatively loose ground, gives one an idea of the thrust that must be exerted by the buckets when they are digging in bedrock. At such times the motion of the boat is so rough that 'sea-legs' are needed.

The stacker, 85 ft. long, by which the tailing is discharged and 'stacked' to a height of 20 ft. above the former surface, is provided with an endless belt 32 in. wide and 182 ft. long. It was made by the Republic company and is 7-ply, with a reinforcement of pure rubber $\frac{5}{16}$ in. thick on the carrying side.

Watching this belt as it carries the tailing to the rear, one sees the pebbles and boulders passing in a steady stream upward, while the sand spouts forth from two sluices, one on each side of the dredge, so as to distribute this finer material laterally and thereby aid in retaining the water in the pond, which is 290 ft. wide. There is so little fine stuff in the gravel that it is difficult to maintain the pond during the dry season, because the tailing-piles are porous. Therefore the undersize from the screen is distributed in such a way as to make a temporary dam across the entire pond. During winter the stacker is covered with canvas (see Fig. 3), which fits over the framework and benefits from the heat generated on the dredge, as well as from steam-pipes that run the length of the stacker.

Going below the third deck, we noted that the screen-

*Through the Yukon and Alaska, by T. A. Rickard, pp. 189-195.

plates are provided with steel auger-bars to induce over-turning of the material and to disintegrate any clay in the gravel. Owing to the large proportion of boulders, these bars are arranged diagonally, so that the boulders may not be carried too high when the screen is revolving, and thus tear out the spray-pipe. Rings placed transversely in the screen impede the flow of gravel and ensur-

ing is absent here. Mr. Ferry stated that tests show no losses from this source; when the black sand of an entire clean up is sifted through a 10 mesh screen, it carries not a cent's worth of gold. The quicksilver is kept clean and lively by means of metallic sodium, and all the gold amalgamates readily. At the office we were shown one nugget of nearly five ounces, worth \$74.17. This was shaped

EAGLE, DECEMBER 31, 1919

thorough washing. The slots in the screens have recently been provided with an exaggerated taper, through the steel plate, so as to prevent clogging. Mr. Ferry has also designed a screen having the angle of the slots in accord with the line of movement of the particles on the curved surface of the trommel, and it has proved effective. The trommel is divided into 15 plates, any one of which, when worn, can be replaced independently of its neighbors. The shaking screen, which follows the trommel, is an innovation on the Yukon dredges, following extensive tests made by Mr. Ferry in 1911 at Dawson. Although the shaker is but 75 inches long by 44 inches wide and often covered with gravel a foot deep, it saves coarse gold, or 'nuggets', that have escaped separation in the revolving screen. Formerly it discharged upon the rubber of the stacker-belt, but the wear was excessive, giving the belt only five months life. Now it discharged upon the manganese-steel of the hopper that feeds the stacker-belt, which now lasts 15 months. The chief loss of gold is in occasional large nuggets and pieces of quartz carrying gold. The manager believes that over 95% of the gold elevated in the buckets is saved on the dredge; moreover, that this represents considerably over 90% of the gold in the deposit. The fine gold of Californian dredg-

ing is absent here. Mr. Ferry stated that tests show no losses from this source; when the black sand of an entire clean up is sifted through a 10 mesh screen, it carries not a cent's worth of gold. The quicksilver is kept clean and lively by means of metallic sodium, and all the gold amalgamates readily. At the office we were shown one nugget of nearly five ounces, worth \$74.17. This was shaped

like an egg, yet it had not rolled off the riffled sluice below the shaker, despite the grade of 2½ inches per foot. Among other specimens were smooth flat pieces resembling safety razor blades; also a number of rough pieces with quartz still clinging to them, suggesting that they had not strayed far from their mother vein. Nor do the riffles draw the color line, for we saw fragments of silver spoons, a half-dollar minted in 1860, dimes and nickels of the 70's and 80's. That such 'savings' are

LOOKING DOWN THE MAIN STREET OF MURRAY, DECEMBER 31, 1919

but when put together, fitted perfectly. While dredging through the O. K. claim, the stronghold of Kid Price and his gun-men, nearly a thousand bullets of all kinds were saved in one clean-up, ranging from the gentle 0.22 up to long-necked slugs that would have suited an elephant hunter.

At 3 p.m., when the dredge was stopped for 10 minutes to grease the lower tumbler and move the swinging lines

to new 'dead-men' or anchors on shore, we were permitted to view the gold-saving tables. They are now enclosed with woven wire, the panner (or 'gold-man') being the sole possessor of a key to this enclosure. It seems that soon after the dredge started, the appearance of coarse gold proved too great a temptation for one of the employees. He was soon apprehended, the gold recovered, and the thief sentenced. Prevention is better than cure. We saw how the small gravel and gold falls through the perforations in the trommel into a 'distributor', from which it is fed onto the 14 tables. These consist of shallow sluices 3 ft. wide and averaging 16 ft. long, the first four tables having a grade of $1\frac{1}{2}$ inches per foot, the grades of the following tables being increased to correspond with the coarser material passing over them. There are seven tables crosswise of the dredge discharging into two sluices running lengthwise, the latter two combining in a long 'tail-sluice' extending about 30 ft. beyond the stern of the boat. This arrangement of tables and sluices is duplicated on the opposite side of the dredge. The gold is arrested by Hungarian rifles placed in the sluices, 26 in. wide. The rifles consist of strips of yellow pine, $1\frac{1}{4}$ by $1\frac{1}{4}$ spaced 1 in. apart, and beveled on top so as to slope opposite to the flow of the gravel, thereby causing an eddy in which the sand remains loose while the gold is given a chance to settle. These rifles are held in a frame of clear pine of $1\frac{1}{4}$ in. cross-section; their life has been doubled by covering the tops with strap-iron $\frac{1}{4}$ inch thick, instead of $\frac{1}{2}$ inch as formerly. Thus protected they wear as well as angle-iron rifles, which have a tendency to pack hard with sand.

In order to catch any gold in the material spilled from the buckets into the well-hole, another series of tables is placed below the dump-hopper. The spill falls upon a grating of manganese-steel, so tapered that gravel small enough may pass into the 'save-all', which is a series of zig-zag sluices, with rifles, supplied with extra water from the 4-in. pump. Nearly $1\frac{1}{2}\%$ of the gold obtained comes from this 'save-all'.

Clean-ups are made at intervals of 10 to 15 days. The rifles are loosened by knocking out the wedges that hold them in place. The concentrate is shaken free and the rifles are hosed. Then the concentrate, a black iron sand associated with the gold, is shoveled and stirred before being 'streamed down', or washed successively over the tables, to one-twentieth its first volume. While this is being done, about 70% of the gold and amalgam proves sufficiently heavy to remain at the upper end of the tables, from which it is shoveled into buckets ready for retorting. The remaining 30% is then separated from about a ton of heavy sand by being washed through a sluice-box equipped with amalgamated copper plate, an amalgam-trap, and a rifle-sluice.

The figures of production are not published by the Yukon Gold Co., the owners of the dredge, but the annual report of Robert N. Bell, the State Mining Inspector, gives the gold output of Shoshone county in 1918 as \$302,000. Of this probably the major portion came from the dredge.

Leaving the dredge we walked about 50 yards south to see the steep rocky rim of a back channel; this sloped similarly to the edge of the main channel in which the dredge is digging. On the north side of the valley, and 300 ft. above it, the reddish banks of old hydraulic cuts indicate the line of the alluvial channel that was the parent of Prichard creek and contributed half its gold, the other half having been derived from the direct erosion of innumerable local veins, as is indicated by specimens of gold-bearing quartz arrested from time to time on the dredge. Two miles above the dredging ground there were gold-quartz mines, the total yield from which is reported to have been \$3,000,000. The most notable were the Golden Chest, Mother Lode, Daddy, and Yosemite.

It was time to start on the return journey. Going down the valley three miles we passed through Eagle, the pioneer mining settlement of the Coeur d'Alene, but now almost deserted. It was a peaceful scene. The few log-cabins that had survived demolition and decay seemed to be asleep in the afternoon sunshine and behind them rose the deeply brooding pine-clad mountains. Three miles farther we came to the north fork, or main branch, of the Coeur d'Alene river, and followed it to the mouth of Beaver creek, thence to Delta, where we rejoined the road over which we had traveled in the forenoon. On Dobson Pass we lingered again to enjoy the view. The lengthening shadows and the quiet of evening gave the landscape a renewed charm. Some day these mountains will relapse into their primeval restfulness, when the mines have been exhausted and the age-long concentration by natural processes has been realized in a brief harvesting by human toil.

(To be continued)

THE production of cobalt is about 500 tons per year for the world, the use of the metal being limited by a comparative scarcity. A report of the Ontario Bureau of Mines shows that the only workable sources known are in Ontario, Missouri, New Caledonia, Belgian Congo, and Schneeberg (Germany); the most important deposits are at Cobalt, Ontario, although the Missouri mines promise to supply the needs of the United States. Though the yield at the Ontario mines is two-thirds of the world's total, the metal is only a by-product. The 1917 production of the mines at Cobalt was 155 tons nickel, 337 tons cobalt, and 2592 tons arsenic, besides 19,401,893 oz. silver. The silver represented a value of \$16,121,013 out of \$18,028,597 for the entire product. Arsenic and silver do not occur in the Missouri ore. This contains copper and lead, with much smaller averages of lead and nickel. The ore of New Caledonia is chiefly oxide, averaging about 3% cobalt. The Belgian Congo mines yield an ore with much copper and about 3% cobalt. The Schneeberg ores also are poor in nickel and cobalt, being richer in bismuth. Compounds of cobalt have served for coloring materials from a remote period. Cobalt has long been employed in the enamel, porcelain, and glass industries, but new demands have arisen in recent years.

Elements of Smelting-Plant Design—II

By OLIVER E. JAGER

THE CHARGE. It having been previously decided that 1000 tons per day is to be the rate of exploitation, or, rather, that the money resulting from the sale of the metals recoverable from this tonnage is to be the average daily earning of the concern, we may proceed with the smelting problem. The ore is assumed to be direct-smelting, and to be divided into two classes: (1) high-grade ore consisting of sulphides in a silicious gangue; (2) low-grade partly oxidized ore with an excess of iron, of which there is less developed than of ore No. 1, the ratio of the available amounts of the two ores being as 100:66. The analyses are as follows:

Ore No. 1	Ore No. 2
SiO ₂ 56	SiO ₂ 14.0
Al ₂ O ₃ 4	Al ₂ O ₃ 1.5
Fe 16	Fe 41.0
S 15	S 26.0
Cu 6	CaO 1.0
	MgO 2.0
	Cu 2.5

The first ore yields 15% fine, undersize of a 2-in. screen; and the second, 10%. Applying these figures to the two ores, we get, for 1000 tons per day:

Ore No. 1.....	600 tons =	90 tons fine plus 510 tons coarse
Ore No. 2 (66% of No. 1)...	400 tons =	40 tons fine plus 360 tons coarse
Total	1000 tons =	130 fine 870 coarse

This shows the relation between the quantities of coarse ore to be smelted in the blast-furnace, and the fine ore to be sintered. A good idea of the quantity and analysis of the sinter will have been obtained previously by small-scale experiments, but we will assume that 90% of the charge to the machines is returned as sinter, thus giving a daily production of 117 tons of sinter. We are now in a position to calculate the furnace-charge, which will give us a large amount of information.

There are two or three methods of doing this,¹⁴ the most usual being the calculation of a slag of a certain silicate degree, and the calculation of a 'type' slag with definite relations between the bases present. Some methods are algebraic, and others are applicable only after the plant has been in operation for some time and the average analyses of the matte and slag have become established. For example, at a certain plant it has been found that the amount of slag produced is 75% of the weight of the charge, and that the slag carries 0.5% sulphur. Using this information, sulphur going to slag can be subtracted from the total sulphur in the charge. After deducting the sulphur volatilized, the remainder will be sulphur in matte. The matte has been found to average 24% S and 30% Fe, hence the weight of matte produced and its iron content are determined. This is a

simple and useful method after the data are once available. I am aware that a charge-calculation appears in the technical press at more or less regular intervals, but generally without sufficient explanation to enable a person unfamiliar with the process to make the calculation on some other ores. For this reason (at the risk of repetition), the present method is given. It is not new, being the 'silicate-degree' method presented in a manner somewhat different from that in the textbooks.

When fluxing a silicious charge, as in the present case, it is usual to make a slag of a silicate-degree as high as compatible with good running. Lime is generally combined as a bi-silicate, while the sesqui-silicate of iron is preferred to the mono-silicate. On the other hand, when a basic charge has to be fluxed, the sesqui- or mono-silicate degrees are adopted, so as to reduce the amount of barren flux to the lowest amount. The formation temperatures and necessary superheat of any contemplated combination, as shown in Hofman's tables, must be considered carefully, or a freeze-up may result. The small amounts of alumina present may be neglected, although, without going into the question of the rôle played by it, alumina is considered here as an acid for the purpose of illustration. In that case, it is usual to multiply the percentage of alumina by 0.6 and call the result silica. Similarly, the percentage of magnesia is multiplied by 1.4 and called lime. These factors can be easily calculated. For example, magnesia as lime: MgO = 40; CaO = 56. Then 40:56::1:1.4.¹⁵ These substitutions must be employed with care; they are not always to be recommended, especially if some troublesome element or combination is present. In case of doubt, it is safer to calculate each element separately. In actual operation, the analytical results must be compared with the calculated; if there is a chronic discrepancy, the inference is that there is something wrong with the premises, and steps must be taken to re-arrange the calculation. After working with a particular combination of ores for some time, it is often found that purely empirical factors can be evolved for various uses, such as with alumina and zinc, for impurities taken up by the matte, etc. The relative amounts of the ores and of the sinter being already fixed, the other ingredients of the charge must be varied to give the required slag. The furnaces will have to run for the first day or two without converter-slag, as none will be available until after the converters have commenced to blow. Converter-slag is included in the present calculation, however, as it will be a regular constituent of the charge under normal conditions. The 200 tons appearing on the

¹⁴Hofman, 'General Metallurgy', p. 484; 'Metallurgy of Copper', pp. 185 and 202; Barr, op. cit., p. 192.

¹⁵Barr, op. cit., p. 179; Hofman, 'Metallurgy of Lead', p. 332.

charge-sheet (Table 2) is a purely arbitrary quantity and is subject to alteration, as will be explained later.

Having brought alumina and magnesia to their equivalents, and multiplied all the quantities out (with the exception of the lime-rock) to the nearest whole number on the slide-rule, commence with the copper column. From the copper 6% is deducted, thus assuming a recovery of 94%. For practical purposes, matte is taken as Cu_2S , FeS , from which we get: $\text{Cu} : 4 = \text{S}$ with Cu , and $\text{S} \times \frac{7}{1} = \text{Fe}$ with S . Copper, having a greater affinity than iron for sulphur, will first take up all the sulphur it requires. The copper in the matte, with its corresponding sulphur, being calculated, pass now to the sulphur column. With a charge of this nature, plenty of blast, and a furnace having no bosh but a slight taper from tuyeres to feed-floor, a good oxidation of sulphur may be expected, say, 80%. It is better to under-estimate the volatilization than to over-estimate it. Sulphur volatilized is subtracted from total sulphur. It will be noticed that the sulphur in the converter slag is added afterward, as it is regarded as not being subject to volatilization. Thirty-eight tons of sulphur now remain, from which is subtracted the 12 tons with the copper in the matte, leaving 26 tons to carry 46 tons of iron into the matte. These two last items are now entered with the other constituents of the matte, and the whole added, giving 131 tons of matte, which it is safe to increase by 5% to cover absorption of any impurities such as small amounts of zinc or lead (if present), and to allow for irregularities in the make-up of the matte, since its composition cannot be considered as definitely represented by the formula $\text{Cu}_2\text{S} \cdot \text{FeS}$. There is $\frac{17}{138} = 34\%$ copper in the matte. Since the iron that goes into the matte is not available for the slag, it is subtracted from the total iron. The calculation now shows that we have 458 tons of silica, 304 tons of iron, and 16 tons of lime to form the slag. It is at this point that the method of the 'silicate-degree' is applied to produce the required slag, namely, a sesquisilicate of iron and a bi-silicate of lime. All available iron is first combined with the proper amount of silica, and the remaining silica is then fluxed by lime. The necessary factors are found in Balling's tables,¹⁶ or can be calculated from their respective formulas:

$$1 : 0.63; 1 : 1.077$$

To calculate the lime-rock required:

$$\text{Fe} \times \frac{9}{7} = \text{FeO}, \quad 304 \text{ tons Fe} = 391 \text{ tons FeO}$$

$$\text{Silica fluxed by FeO} = 391 \times 0.63 = 246$$

$$\text{Silica fluxed by CaO} = 16 \times 1.077 = 17$$

—
Total 263 tons

Total silica = 458 tons; $458 - 263 = 195$ to flux by lime-rock. $195 : 1.077 = 181$ tons CaO required. The lime-rock contains 50.4% available CaO , so that the lime-rock required = $\frac{181}{50.4\%}$, or 359 tons.

'Available' lime is the amount remaining after the

silica in the lime-rock has been fluxed. To calculate it the procedure is the same as before. Since it contains 1% Fe, this will flux $1 \times \frac{9}{7} \times 0.63 = 0.8$ silica, leaving 1.7 to flux with lime; $\frac{1.7}{1.077} = 1.6$; $52 - 1.6 = 50.4\%$ available lime.

This 359 tons of lime-rock is now entered on the sheet, and the amounts of silica, iron, and lime put down. The result of the final addition is that we have 467 tons of SiO_2 , 396 tons of FeO , and 203 tons of CaO to form the slag. It is usual to say that the silica, iron oxide, and lime in the slag will add up to 90%, but if other bases have been included, as in the present case, the total will be more, say, 95%. Dividing 1066 by 95% gives 1122 tons of slag formed. The quantities 467, 396, and 203 are then each divided by 1122 to obtain the percentage of SiO_2 , FeO , and CaO , respectively, in the slag. To prove the silicate-degree correct, proceed as follows: $(18.1 \times 1.077 + (35.3 \times 0.63)) = 41.7$, which is a sufficiently close check.

In calculating the ratio of concentration, only new materials are considered. Any matte or other eupriferous revert on the charge must be allowed for, as it has been produced from some previous charge. It would be incorrect to say that 987 tons of raw material (ore and sinter) produced 138 tons of matte, as 12 tons of this matte came from the 4 tons of copper contained in the converter slag; the new matte produced from the raw material is therefore 126 tons, so that 7.8 tons of raw material make one ton of matte. Sulphur on the charge means the ratio of sulphur available as fuel to the total weight of the charge. Since 142 tons of sulphur are burned off, the percentage will be $\frac{142}{1546} = 9.2\%$. Copper on the charge means the proportion of total copper in the charge. The production of slag is found to be 72.6% of the weight of the materials charged. Coke is not included in any of these totals, as it is fuel, and is always considered an extra. The matte-fall is 11%; this means that 11% of the material flowing from the tap-hole is matte. Some charge-calculations show matte-fall as the ratio of matte to total charge. This may be a useful figure to have, but it is not matte-fall, which is the ratio of matte to the matte-plus-slag produced by the furnace. The fluxing of coke-ash is a refinement not generally adopted in copper work, so it is not considered here.

We are now in a position to get information from this charge-sheet. From the amount of sulphur present, it is clear that the ore-mixture is amenable to treatment by the semi-pyritic process. The sulphur on the charge (volatile sulphur), being about 9%, signifies a considerable generation of heat, so that the coke can probably be reduced from the estimated 10%, though it would be safer to estimate the coke-requirements for this tonnage at 155 tons per day. The matte-fall is sufficient to keep the tap-hole in good condition for free running, and the matte is suitable in grade for treatment in basic-lined converters, which will have to treat 138 tons of matte per day. The ratio of concentration is a little low, but may be left at this point for the present. It happens that

¹⁶Liddell, 'Metallurgists & Chemists' Handbook', p. 511.

the slag analysis has come out satisfactorily as regards the relative proportions of iron and lime; a slag of this analysis should run well. The production of slag will be 1122 tons per day. To treat 1000 tons of ore, 1546 tons of charge must go through the furnaces. The 138 tons of matte contains 46 tons of iron that must be slagged in the converters. The converter slag is estimated to contain 44% Fe, so that the daily quantity of slag made is 105 tons. As this slag will contain 25% SiO_2 , there will be required 26 tons of silica, or, say, 28 tons of quartz at 93% SiO_2 . The quantity of converter slag being about one-half that taken on the charge-sheet, there must be a

balance. Of the 12% apparently lost at the converters, there is, of course, a good proportion recovered in the converter slag, cleanings, and the dust. No account has been taken here of the last two items, and for the sake of simplicity, any consideration of the precious metals has been purposely omitted.

It is apparent, of course, that the above is not the only solution of the problem. The correct method will be that which shows the greatest final profit. If power is expensive, it would be advisable to consider the making of a higher-grade matte (with a consequent higher slag loss), which would call for more sinter and less of No. 2 ore on

TABLE 2 CHARGE SHEET

								$\frac{50}{1546} = 3.2\%$			

re-calculation using the smaller figure instead of the 200 tons. The result is that while the composition of the slag is not materially altered, 20 tons more lime-rock must be used, making the daily requirement of lime-rock 379 tons. As the amount of converter slag available will vary from day to day, this discrepancy in the preliminary calculation is of little importance, except to emphasize the fact that sufficient lime-rock must be arranged for. Of the 47 tons of copper contained in the matte, about 88% will appear as blister copper, giving a daily production of 41.36 tons, thus giving the total recovery of about 90% for the whole plant. It is difficult to give recovery figures that will be useful, as there are many variables to be considered. It is assumed that the flue-dust and converter slag will be treated as fast as they are made, so that there may be no undue amount of copper tied up in these sec-

the charge. This would require more fine ore than is available under present conditions, so that the cost of crushing some No. 2 ore would have to be gone into. Making higher-grade matte would produce less converter slag, the decrease of which on the furnace-charge has been known, in certain cases, to have a bad effect on the speed of the furnaces. High-grade matte permits less ore to be smelted in the converters, which brings up another point. Quartz was mentioned previously as the converter flux, though, of course, it would not be considered while there was an ore such as No. 1 available, so that the use of a large amount of this ore in the converter is another variation of the problem, which introduces the consideration of just how far it pays to use the converter as a smelting appliance. The principal debit against the operation is the cost of power; the credit is the eliminated

cost of blast-furnace smelting to matte. It may be mentioned here that the amount of silica in the converter slag is dependent, to a certain extent, on this question. If only barren flux is available, the silica in the slag would be kept as low as possible; whereas, when using an ore yielding a profit on treatment, the silica would be run higher, as it would be desirable to smelt a considerable amount of this ore in the converter. To produce more of No. 1 ore, the mine would have to be called upon to rearrange its work. Again, if No. 2 ore can be cheaply mined, it would be advisable to consider the sintering of a larger quantity in order to get more iron for the slag, thus reducing the amount of lime-rock required. These and other permutations must be considered as far as possible before commencing operations, though there are some which cannot be properly calculated until cost data are available. In all cases the process must be definitely mapped out in order to get the information required for the design of the various appliances. Some examples will now be given to illustrate this.

SIZE OF FURNACE. For a charge of this nature, the width of the furnace should be about 52 inches. The furnace should have straight sides that slope outward from the tuyeres to the feed-floor at the rate of about $\frac{3}{4}$ in. per foot. The height from the tuyeres to the top of the jackets should be about 13 ft. Since there are no refractory elements in the ores, a duty of 6 tons per square foot of hearth-area per day may be taken in calculating the furnace-capacity required to treat 1546 tons of charge per day. At this rate, 258 sq. ft. of hearth-area must be provided. Since the width of the furnace is 4.33 ft., the length must be 59.6 ft., which would suggest two furnaces each 30 ft. long, or three of 20 ft. The advantage of a long furnace has been demonstrated at Anaconda,¹⁷ but a single furnace 60 ft. long could scarcely be recommended in the present case. The weak point of a single-furnace plant is that if an accident happens, the blast-furnace department suffers a complete shut-down. In a two-furnace plant, the stoppage of one furnace means a 50% shut-down only. This line of reasoning must not be taken as favoring a multiplicity of units; judgment must be used in deciding what would be best under the circumstances. Two 30-ft. furnaces would be a good arrangement, were it not for the fact that there would be then no allowance for time lost in repairs, or otherwise; the two furnaces would have to be in blast 100% of the time to treat the required tonnage. Mention has already been made of the necessity of allowing some leeway in this respect; also, it is natural to expect that the tonnage to be smelted will increase as the mine develops. So that it would be safe to add 10% to the amount of furnace capacity, and provide 66 ft. of furnace, dividing it into three units each 22 ft. long. Sufficient blast-furnace plant has now been provided to treat 1715 tons of charge per day, which means that, over a given period, two furnaces will run continuously and the third furnace will run 70% of the time. It has been my experience that a certain amount

of extra furnace-capacity can always be used. General managers have a habit of producing some extra tonnage from somewhere, so that a 'stand-by' furnace soon becomes a 'regular' furnace, and the unfortunate furnace-superintendent has to get his repairs done as best he can. It will be noticed that no extra capacity has been provided for the treatment of the flue-dust that will come back to the blast-furnaces after being sintered. Allowance must be made for it at the sintering-plant, but it is already taken care of at the blast-furnaces by our having considered the 'gross' charge as 'net' charge. We have assumed that the furnaces will treat the total charge fed to them, whereas they will smelt actually the gross charge less the flue-dust produced. The small amount of flue-dust from the converters would be treated in the same department, for which reason it is good practice to have a separate flue for the converters, so that the rich flue-dust can be kept to itself and cleaned-up before the end of each month.

CONVERTERS. One Pierce-Smith converter of the barrel type, 10 ft. diameter by 26 ft. long, would be capable of treating the daily production of 138 tons of matte. This statement applies to a new vessel; after being in operation for some time the capacity will be less, as the vessel will become more or less crusted and filled. To ensure steady output and prevent loss of time during repairs, two such vessels should be provided. Proper arrangement should be made for getting the flux into the converters, either by silica-guns or by pipes discharging into the mouths. Provision must be made for drying the flux going to the converters, as wet material is liable to cause unpleasant explosions. Since the converter slag is to be returned to the blast-furnaces, there must be provided suitable appliances for casting, breaking, and loading 105 tons per day. The capacity of the cranes is estimated from the data already obtained. Assuming that the furnaces and converters will be in the same building, it will be necessary to move 138 tons of matte from the settlers to the converters, and 105 tons of slag from the converters to the casting department. Since the introduction of the basic converter the size of cranes has been diminished, as there are no heavy vessels to move for re-lining. The required lifting-power of the main hoist will depend largely on the size of the ladles and boats in use on the converter-floor; the auxiliary hooks are used for light lifts and for dumping. No general figures will be given for the lifting-capacity, as each case must be decided in conjunction with the other details of the process. Besides moving matte and slag, there is always other work for the crane, such as moving boats of scrap and clean-up material, or, perhaps, handling flux and loading converter slag into cars. Once the details of the process have been worked out, the number and length of the trips to be made can be estimated. By using the speeds of travel and hoist (as supplied by the makers), it can be calculated whether the work, as laid out, is within the capacity of a single crane, and if not, how many cranes will be required. Allowance should be made for oiling and repairs, if the

¹⁷L. S. Austin, Trans. A. I. M. E., July 1906.

crane is to be properly maintained, as a break-down may prove costly through interfering with the regular output. For this reason an extra crane is often a good investment. D. C. is preferable to A. C. for crane power.

SINTERING-PLANT. One Dwight Lloyd standard straight-line machine, 42 in. by 261 in., should have a capacity of from 80 to 90 tons of this charge per day. There are 130 tons of fine ore to be treated, with an average sulphur content of 18%. Blast furnace flue dust is also to be sintered, but, as the ore is all screened, the production of dust should be small. Two sintering machines, therefore, should be provided, and the sintering-plant laid out so that more machines may be added in case modification in the process of treatment demands it. Bins and a proper belt-conveyor equipment for making suitable mixtures are part of every modern sintering-plant. The machines should be placed high enough to allow for the screening-out and recovery of the resulting fine for re-treatment.

BLOWERS. The amount of air required for the blast-furnaces may be calculated approximately, as follows: The oxygen of the air is used to oxidize the sulphur, carbon, iron, manganese, zinc, lead, and other oxidizable elements, as shown on the charge-sheet. Referring to this, we find that there are 142 tons of sulphur volatilized or (mostly) burned, 155 tons of coke, at, say, 85% fixed carbon or 132 tons of fixed carbon consumed, and 308 tons of iron oxidized to FeO for slagging.¹⁸

Sulphur	142 tons	$S + O_2 = SO_2$	$\frac{142 \times 32}{32}$	142 tons SO_2 is required
Carbon	132 "	$C + O_2 = CO_2$	$\frac{132 \times 32}{12}$	352 " "
Iron	308 "	$Fe + O = FeO$	$\frac{308 \times 16}{56}$	88 " "
Total			582	

$$\frac{1.757 \times 2000}{0.0807} = 43,510 \text{ cu. ft. of air per minute for 1546 tons of charge}$$

For more exact calculation, corrections should be made for temperature and pressure.¹⁹ This is necessary if the smelter is situated at any considerable altitude above sea-level. Allowance should also be made for the sulphur that passes off as elemental sulphur; all the sulphur has been considered here as combining with oxygen; actually, the amount would be less, as a certain portion will pass off uncombined, depending on the amount of pyritic minerals in the charge.

Since there is provided a capacity of 1715 tons of charge per day, the above amount of air must be increased to 48,310 cu. ft. But the air-efficiency may be expected to be about 66.6% only, so that the total quantity of air will be 72,520 cu. ft. The term 'air-efficiency' must not be confused with 'blower-efficiency': the former is the ratio of the amount of air doing useful work in the furnace, to the total amount of air blown in; 'blower-efficiency' is the ratio of the air delivered, by the blower, to the quantity of air the machine is rated to deliver by the maker, or, more correctly, the ratio of

delivery to displacement. So that, to run all three furnaces, 72,520 cu. ft. of air per minute must be provided. The specification for the blower would call for this amount of air to be delivered against a pressure of, say, 14 oz., although the average pressure during operation would not reach that figure. The method of calculating the amount of air is not always employed, empirical figures being generally used in estimating the size of the blowers. Such figures as 1100 cu. ft. per minute per linear foot of hearth, and 260 cu. ft. per minute per square foot of hearth, are fairly reliable. Applying these figures to the present case we get 66 linear feet of hearth at 1100 cu. ft. per minute = 72,600 cu. ft., or 286 sq. ft. of hearth at 260 cu. ft. per minute = 74,360 cubic feet.

For immediate requirements, two turbo-blocos, each with a capacity of 36,000 cu. ft. per minute, might be recommended, but the actual selection of the machines may be influenced by the prevailing market conditions, the nature of the bids submitted, and the probability of an increased output in the near future.

The air required for the converters may be calculated in a similar manner, using for the calculation the tons of sulphur, of iron, and of other oxidizable elements in the 138 tons of matte and in the ore or flux added. The air-efficiency is higher in the converter than in the blast-furnace (where a certain amount of air is bound to escape uselessly along the jackets), so that from 80% to 90% of the air entering the converter may be assumed to be doing work. This refers to modern basic-lined converters, which have a higher air-efficiency than the old acid-lined vessels. There is one point that must be taken into account in estimating the required size of a blower for converters, namely, that the vessels do not blow all the time. Using the daily tonnages of matte and flux, and calculating as shown above, there will result the quantity of air necessary for 24 hours of operation. Actually, a converter does not blow 24 hours per day, as time is lost in charging, skimming, and pouring copper, these delays being part of the process and inevitable. Further delays may occur for repairs to the lining or turning-gear, so that a period of from 16 to 20 hours per day, according to conditions, is all that it is safe to take as representing the blowing-time. That is to say, the 24-hour production of matte must be treated in, say, 16 hours; hence the calculated amount of air to be delivered must be increased proportionately.

SUNDRY APPLIANCES. Two examples only will be given under this heading, namely, charge-cars and slag-pots. There are several methods of charging a furnace,²¹ but we will assume that charge-cars dumping by compressed air have been selected for the work. Under the present conditions a charge should form in the furnace a layer from 18 inches to two feet thick. Assuming a column of charge 10 ft. high, the width of the furnace at the surface of the charge will be 5 ft. 7 in. (jackets

²⁰C. C. Christensen, 'Designing Small Copper Smelters';
'E. & M. J.', Jan. 30, 1915.

¹⁸Richards, 'Metallurgical Calculations'; Part III, chap. 1.

¹⁹Kent, 'Mechanical Engineers' Pocket Book'; p. 581.

sloping at $\frac{1}{4}$ in. per foot $\frac{1}{4}$, and the area will be 122.8 sq. ft. One hundred and fifty pounds of charge per square foot of area is a good average figure to use, so that the weight of the charge will be $122.8 \times 150 = 18,420$ lb. Allowance must be made for coke and for extra slag, or for the use of a larger charge, so that the 18,420 may well be increased to 22,000 for the purpose of estimating the size of the charge-car. As the side of the furnace will be closed by four doors, a charge will be divided among four cars each containing 5500 lb., which, at an average of, say, 24 cu. ft. per ton, will require a volume of 66 cu. ft. If desired, the approximate weight per cubic foot of charge may be calculated by using figures given for the cubic feet in a ton of broken ore, not ore in place.²² To the figures given in the reference just quoted may be added some that were determined under actual conditions in a charge-car:

	Pounds per cu. ft. in charge-car
Heavy pyritic ore in gabbrro.....	140
Gabbrro.....	110
Converter slag (30% SiO_2).....	130
Coke.....	30

The size to which a commodity is broken will regulate its weight per cubic foot, since the finer it is crushed the less will be the interstitial space. For this reason, differences may be noted in tables of such figures by different authorities. Assuming the charge to measure 24 cu. ft. to the ton, we find that, at the top of a 10-ft. column in the furnace, a charge of 20,000 lb. will form a layer about two feet thick, while one of 17,000 lb. will measure about 20 in. thick. The size of charge that will give the best results in the furnace will be determined, of course, by actual experiment after the plant is in operation. Running three furnaces, there will be required two trains of 12 cars each, or 24 cars. As these cars will be working continuously during the greater part of each month, at least four extra cars should be provided to allow for repairs and the renewal of worn-out parts.

Of the two methods of slag-disposal, granulation and haulage, we will assume that the latter has been selected. From the charge-sheet we find that the production of slag will be 72.6% of the charge, or 1245 tons when smelting 1715 tons of charge in three furnaces, which gives an hourly production of about 52 tons of slag. The adoption of a few pots of a capacity of about 20 tons each is to be preferred to that of a long string of small pots, so that the flow of slag may be taken at three pots per hour. The number of pots required would work out something like this:

	Slag-pots
At furnaces.....	3
At dumps or returning to furnaces.....	3
Spare, in case of repair or accident.....	2
Total to commence operation.....	8

As the dump grows, the haul will be longer, although the time-factor is well taken care of by the large pot. If haulage is by electric motor, the pots should be arranged to dump by the same power. It is convenient to have one pot that dumps over the end of the track, to facili-

tate the extension of the track along the line of its direction. A good pot of this type is the Dewhurst, as used in some plants in Australia. To calculate the required volume of a pot for the slag under consideration here, the specific gravity of the slag may be taken at 3.5.

STORAGE-BINS. These are necessary to protect the furnaces against irregularities in the receipt of ore, flux, or fuel. The amount of storage provided depends on the distance from the source of supply, and the probability of interruption or variation in the supply. In a plant where the furnace-charge is bedded, the number of bins will be small, as the majority of the materials will go direct to the beds. Under ordinary circumstances it is usual to provide bins to hold a supply sufficient for three or four days, but this should be increased if there is any serious danger of interruption to the delivery of materials. The farther the plant is from the mine, the lime-quarry, and the coke-ovens, the more liability there is for interruption in the regular transportation. Since the running of furnaces on reduced blast while waiting for materials is not conducive to large dividends, the amount of storage to be provided, both in bins and in stock-piles, is a matter that must be considered carefully. In case of a strike at the mine or a wash-out on the railroad, large stock-piles are comforting things to have in the smelter-yard, provided means are at hand to reclaim them, but there is a limit to the amount of money that it is advisable to tie up in this manner. Local conditions will affect policy in this regard, although it may be said, in general, that there is usually a liberal allowance made in the case of fuel, so that a good stock of coke is provided.

The storage-bins from which the charge-cars are loaded should be conveniently near to the furnaces. The chutes should be spaced to coincide with the centres of the charge-cars when a train is spotted for loading. While there is something to be said for each of the various types of bin, the flat-bottomed bin with a side-discharge is hard to beat. The trouble with a bottom-dump bin is generally with the gate. Putting a sloping bottom in a side-discharge bin reduces its capacity considerably, and the sloping bottom requires extra support; also, it must have protection from the falling material during filling. The flat-bottomed bin with side-discharge will always have a layer of material to protect the bottom; it will discharge well and generally have some material left in it that can be drawn upon in an emergency by putting shovellers to work. Charges are usually weighed by weighing-hoppers or by track-scales; in the former case more head-room is required. In calculating the capacity and number of bins required, the weight per cubic foot of broken or loose material must be used. Since coke is frequently loaded directly from railroad-cars into the coke-buggies, the supply of coke in the storage-bins may not be drawn on very often, but it is a good precaution to have it there. Under ordinary circumstances, in the present case, a sufficient number of bins would be provided to hold the following tonnages:

	Tons
Coke.....	600
Lime-rock.....	1,800

²²Liddell, op. cit., p. 175.

Ore No. 1	100
Ore No. 2	100
Sinter	100
Converter slag	100
Converter flux	100
Fine ore, stored at sintering plant bins	100

CONCLUSION. It is apparent, of course, that before commencing any estimate or design, it is necessary to have as complete a set of data as is possible on all the phases of the problem. Included in these, and of especial importance, are the local conditions, such as the cost of labor and of supplies, the magnitude of the operations (both proposed and probable), and other factors of like nature mentioned previously in this article. The more accurate and complete the data, the more correct should be the estimate, although it must be admitted that to forecast accurately every detail of a process is extremely difficult, if not impossible. A flow-sheet is of assistance in revealing incongruities, or in calling attention to omissions, in the process, and should be drawn up as soon as the general outline of any proposed set of operations has been determined. It should show not only the path followed by all the materials, but also the figures of tonnage and analyses (calculated or assumed) included with every item. These graphic representations are useful in comparing two or more different schemes. In some cases where sufficient data are unobtainable, recourse must be had to the performance of a neighboring plant, or to a comparison with a similar enterprise elsewhere, making allowances (plus or minus) for local differences, in doing which experience and judgment are of the greatest value. Assumptions sometimes must be made in order to get an outline of the work, but the experienced engineer is always careful of his premises, as he knows full well that upon his judgment in such matters hang all the law and the profits.

MINING OF ANTIMONY ORES in the United States practically ceased in 1918. The amount produced in that year was only 190 tons of ore with a content of 50 tons of antimony, as compared with 1600 tons of ore in 1917 and 5000 tons in 1915. About 2500 tons of metallic antimony was produced by smelters in the United States in 1918, almost entirely from foreign ores. The imports were large, amounting to 2734 tons of 50% ore, and 13,374 tons of metal. Mexico and Bolivia provided most of the ore imported; the metal came chiefly from China. According to a statement made public by the U. S. Geological Survey, the greatest demand for antimony is for war purposes, chiefly in the manufacture of shrapnel bullets. The peace-time consumption of the metal amounts to only a small proportion of its war-time consumption. Antimony oxides are used in making glass, enamel, and paint; the sulphides in making rubber; and the metal in certain alloys, such as type metal, babbitt, Britannia metal, and hard lead. The great importance of antimony as a war metal is shown by the total world's production in recent years. In normal pre-war years this amounted to about 20,000 metric tons per year. In 1916, however, the estimated world's production was 78,700 tons. This large output exceeded even the war demand, and in 1917

the production had fallen to 54,300 tons. More than half the world's supply comes from southern China, principally from the Province of Hunan. France in 1913 produced about a quarter of the world's supply, and during the War large deposits were developed in Algeria. Mexico is the next in importance and in 1913 contributed over one-tenth of the world's supply. Bolivian deposits were extensively developed during the War. The U. S. Geological Survey's annual report on antimony, by Henry G. Ferguson, has just been issued.

Potash to meet the industrial requirements of the United States, was formerly imported almost entirely from Germany. Purely from a standpoint of nationalism it is to be hoped that the United States will some day be able to throw off the German yoke. But high-priced potash increases the expense of producing crops, which in turn bears upon the cost of living. Thus it is a debatable question whether the infant potash industry is entitled to receive the tariff protection it requires, at the expense of a further rise in the cost of living. Dr. H. J. Wheeler, fertilizer expert of the American Agricultural Chemical Co., recently said that the United States has many undeveloped possibilities of a future potash supply fully adequate for our national needs, but no one of these offers hope of furnishing any considerable amount at prices which will permit of serious competition with German muriate of potash (containing 50% of potash), which can be landed in this country at \$12 to \$15 per ton and still yield a living profit to the producers. Prior to the War the United States was importing from Germany for agricultural purposes about 226,000 tons of actual potash in the form of German potash salts, which was equivalent to about 452,000 tons of muriate of potash. While there is sharp divergence of opinion among authorities as to the actual need for potash in agriculture, it is significant to note that a careful estimate by States places the minimum requirements of the entire country for agricultural purposes at 147,243 tons per year of actual potash (potassium oxide), equivalent to 291,486 tons of muriate of potash, or about 736,215 tons of the crude potash salts now being produced from the Nebraska lakes. In other words, the incompressible minimum requirement is very much more than half the annual consumption for such purposes prior to the War. As against this minimum requirement and annual importations of 226,000 tons of actual potash before the War, there was produced in the United States in 1917, the equivalent of but around 60,000 tons of muriate of potash. In the year 1918 the output was perhaps 120,000 tons, equivalent to about 60,000 tons actual potash. The current year will show a further increase, but this will be considerably short of amount required. Thus, from the standpoint of both volume and economy of production, the American potash producer remains at a very decided disadvantage as compared with his German competitor, and the conclusion is obvious that emancipation of the American farmer from German potash domination has not yet come.

Statistical Review

Production of Base Metals for 1919*

Copper

The production of copper in the United States in 1919 was markedly smaller than in 1918, according to preliminary figures and estimates collected by B. S. Butler, from all plants that make blister-copper for domestic ores, or that produce refined copper. At an average price of about 19 cents per pound, the output for 1919 had a value of \$243,000,000, as against \$471,000,000 for 1918.

The figures showing the smelter production from domestic ores represent the actual output of most of the companies for the first 11 months of the year and the estimated output for December. A few companies gave no figures for November, but furnished estimates of the combined output of November and December. The production of blister and Lake copper from domestic ores was 1,278,000,000 lb. in 1919, against 1,908,000,000 lb. in 1918 and 1,224,000,000 lb. in 1913.

The supply of refined copper (electrolytic, Lake, casting, and pig) from primary sources, domestic and foreign, for 1919, is estimated at 1,800,000,000 lb., compared with 2,432,000,000 lb. for 1918 and 1,615,000,000 lb. for 1913.

According to the Bureau of Foreign and Domestic Commerce, the imports of copper in all forms for the first 10 months of 1919 amounted to 346,855,000 lb., against 575,800,000 lb. for the 12 months of 1918.

The exports of pigs, ingots, bars, plates, sheets, rods, wire, and like copper products for the first 11 months of 1919, as determined by the same bureau, amounted to 496,350,000 lb.; the exports for the 12 months of 1918 were 744,429,000 pounds.

At the beginning of 1919 about 180,000,000 lb. of refined copper was in stock in the United States. Adding this quantity to the refinery output for the year shows that the total available supply of refined copper was about 1,980,000,000 lb. On subtracting from this total the exports for the first 11 months and the estimated exports for the last month, and assuming that there was no change in stocks, it appears that the supply available for domestic consumption in 1919 was considerably less than the 1,661,000,000 lb. available in 1918.

Lead and Zinc

MINE PRODUCTION. The mine output of lead and zinc in the United States declined greatly in 1919, following a sharp decline in 1918, according to a statement compiled by C. E. Siebenthal from reports and estimates by producers and from the records of the Bureau of Foreign and Domestic Commerce.

The output of 'soft' lead by mines of the Mississippi Valley and Eastern States was 217,000 short tons, and that of argentiferous lead by mines of the Western States was 208,000 tons, a total of 425,000 tons, compared to 267,184 tons and 314,470 tons, respectively, a total of 581,654 tons, in 1918, and to 273,095 tons and 377,854 tons, respectively, a total of 650,949 tons, in 1917, a decrease of over 156,000 tons in 1919, compared with a decrease of 69,295 tons in 1918. The south-eastern Missouri district made the largest production, 153,500 tons, and the Coeur d'Alene district of Idaho was next, with

THE MISSISSIPPI VALLEY LEAD AND ZINC FIELD

86,000 tons. The imports of lead in ore and bullion were about 63,000 tons, as compared with 93,367 tons in 1918.

The recoverable zinc content of ore mined in 1919 was about 569,000 tons, compared with 632,243 tons in 1918 and 713,359 tons in 1917. The output of the Eastern States was 116,500 tons, that of the Central States was 318,000 tons, and that of the Western States was 134,500 tons, compared with 124,268 tons, 302,662 tons, and 195,313 tons, in 1918. The output of the Central States gained slightly over 1918, by an increase of about 20,000 tons in the Joplin district. The gain in this district was a result of an increase in the output of Oklahoma, which reached a total of over 189,000 tons, the largest zinc output ever made by any State. Oklahoma produced 161,401 tons in 1917 and Missouri produced 155,960 tons in 1916. In 1919 Montana apparently produced over 88,000 tons and New Jersey over 87,000 tons of zinc.

The imports of zinc in ore fell off from 24,809 tons in

*From preliminary reports of the U. S. Geological Survey.

1918 to 17,000 tons in 1919. The zinc content of ore imported from Mexico dropped from 18,426 tons in 1918 to 11,000 tons in 1919.

REFINED LEAD. The production of primary domestic desilvered lead in 1919 was 218,500 short tons, of soft lead 151,000 tons, and of desilvered soft lead 61,500 tons, making a total output from domestic ores of 131,000 tons of refined lead, compared with 539,905 tons in 1918, made up of 282,024 tons of desilvered lead, 210,463 tons of soft lead, and 47,418 tons of desilvered soft lead. The output of lead smelted and refined from foreign ore and bullion was 62,000 tons, compared with 100,290 tons in 1918. The total lead smelted or refined in the United States was thus 493,000 tons, compared with 640,195 tons in 1918. The production of antimonial lead was 10,000 tons, against 18,570 tons in 1918. The exports of lead of foreign origin were 44,000 tons and of lead of domestic origin 14,000 tons, compared with 40,480 tons and 64,194 tons, respectively, in 1918, a decline of nearly one-half in the total exports. The quantity of lead available for consumption in this country was 456,000 tons in 1919, compared with 493,625 tons in 1918. In comparing the quantity available for domestic consumption in 1919 with that available in 1917 and 1918, it should be noted that considerable quantities were shipped abroad in those years for the use of the American Expeditionary Force, which, not being recorded as exports, are included in the apparent consumption.

The average price of lead at New York in 1919 was 5.8c. per pound, compared with an average price of 7.1c. in 1918. At the beginning of 1919 lead was quoted at 5.75c., but it went slightly below 5c. in April and May, after which it steadily climbed until the close of the year, when it was quoted at about 7.5c. This advance in price, despite the falling off of exports and the cessation of shipments to the American forces abroad, would seem to indicate that the production has been nicely adjusted to the needs of the domestic building program.

The Flint Mill & Furnace Co. built a 20-ton Fink furnace at Wauwatosa, Wisconsin, in 1919 to treat Wisconsin lead concentrate. The Mineral Point Zinc Co., at Depue, Illinois, operated a lead blast-furnace upon valuable lead-bearing zinc-retort residues. The U. S. Smelting, Refining & Mining Co. acquired the electrolytic lead refinery at Grasselli, Indiana, from the U. S. Metals Refining Co., near the close of the year. Many lead smelters were closed for longer or shorter periods during the year or ran at partial capacity. The Globe plant of the American Smelting & Refining Co., at Denver, Colorado, was permanently closed early in the year.

ZINC. The production of primary metallic zinc from domestic ores in 1919 was 446,000 tons, and from foreign ores 13,000 tons, a total of 459,000 tons, compared with 492,405 tons and 25,522 tons, respectively, a total of 517,927 tons, in 1918. Of the output of domestic zinc in 1919 nearly 27,000 tons consisted of electrolytic zinc, as compared with 38,916 tons in 1918. In addition there was an output of over 17,000 tons of re-distilled secondary zinc compared with 9597 tons in 1918, making a total

supply of distilled zinc in 1919 of 176,000 tons, of which about 15,000 tons was of high grade, 21,500 tons of intermediate grade, 77,500 tons was select and brass special, and 329,000 was prime western. The production of the corresponding grades in 1918 was 129,023 tons, 68,947 tons, 98,584 tons, and 230,230 tons, respectively. Of the total output of primary zinc in 1919, about 118,000 tons was made in Illinois, as against 141,844 tons in 1918; 43,000 tons in Kansas as against 29,149 tons; 119,000 in Oklahoma as against 139,066 tons; and 65,500 tons in Pennsylvania as against 77,312 tons in 1918.

The exports of zinc made from foreign ores were 17,500 tons and those of zinc from domestic ores were 127,000 tons, compared with exports of 26,837 tons of foreign and 80,244 tons of domestic zinc in 1918. The exports of domestic zinc include 20,000 tons of sheet zinc as against 13,875 tons in 1918. The stock of zinc at smelters and in warehouses at the end of November was 51,500 tons as against 59,651 tons on June 30, 1919 and 41,241 tons at the close of 1918. The apparent consumption of primary zinc during 1919 was 304,000 tons, compared with 423,361 tons in 1918 and 413,643 in 1917, a quantity somewhat below the pre-war figure, which for the years 1910-1913 averaged 327,255 tons.

The average quotation for prime western zinc at St. Louis in 1919 was 7c. per pound, compared with 8c. in 1918. The price of prime western zinc began the year 1919 at 7.7c. in the St. Louis market, declined below 6c. in May, rose to nearly 8c. at the end of July, dropped back nearly to 7c. late in September, and then improved to the end of the year, closing at about 8.7 cents.

The decrease in smelter stocks since June 30, coupled with the practical absorption of the large Government stocks held by the Ordnance Bureau at the beginning of the year, taken with the continuance of large exports and the growing demands of the domestic building industry, caused the stiffening of prices and the increase in operating capacity during the last quarter of 1919. The exports of zinc averaged over 11,500 tons monthly. Great Britain made the largest demand for our exports of slab zinc, taking the greater part of them doubtless in rebuilding her export trade in galvanized products, and France, Japan, and Italy were next in order. Italy was the largest importer of sheet zinc from the United States in 1919, Great Britain was a close second.

The 'Metal Bulletin' of London, under date of December 16, 1919, calls attention to the critical state of the British zinc-smelting industry, and, considering the possibility of obtaining zinc from other countries, points out that Germany, on account of lack of fuel and ore, is producing only about 3000 tons per month, no more than her own needs; that Belgium, producing now about 3000 tons per month, will need the whole of her output in 1920 for sheet zinc; that France, on account of the destruction of her works and lack of coal, cannot be counted on for supplies in 1920; and that works in Holland are closed because of the prohibitive price of coal. The inference is that the United States will continue to export zinc to England at least for a year.

The Blue Sky Law

Senator Kenyon has introduced a bill, S. 3702, for the purpose of giving some protection to persons having a limited capital to invest, who have frequently been victimized by dishonest and unscrupulous salesmen of worthless or questionable stocks. The text of the bill is as follows:

To regulate the issuance of stock by corporations engaged in interstate commerce.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That whenever an offering is made to the public of an original issue security by any corporation engaged in interstate commerce the issuing company shall file with the United States Postmaster at its legal address for public inspection, and also with the Federal Trade Commission at Washington, a statement signed by its responsible officers or promoters showing—

(a) The purpose for which the corporation is organized;

(b) The officers and directors or promoters, and their residences and whether securities are held by a holding company or whether it holds securities of another corporation, naming such corporation; what commission, if any, the officers, directors, promoters, or agents are to have for the organization of said corporation and the floating of said securities;

(c) The latest balance sheet of the issuing corporation; such statement shall show in detail all payments for tangible and intangible property, good will, promotion fees and any and all other agreements for the disbursement of money except as shown in (d) hereinafter;

(d) The purposes to which the proceeds of the sale of the new security are to be devoted;

(e) The terms of the flotation showing the price at which the securities are sold by the issuing corporation; the estimated expense of the flotation; the name of underwriters, if any, and the terms of underwriting and the names of and terms by which sub-underwriters, syndicates, bankers, brokers and others deal in the original sale of such securities.

Sec. 2. That the statement provided for in section 1 shall be a public record; that any prepared, prospective circular offering such securities for sale must contain the information described in sub-divisions (a), (b), (c), (d), and (e) of section 1; and that a copy showing the same must be attached to each bond, certificate of preferred or common stock and to each receipt or certificate evidencing a subscription to such security. Any false or mis-leading statement in such statement herein referred to shall constitute perjury as to each and every person issuing or signing the same. It shall be the duty of the United States district attorney of the district in which such person or persons may be found to reside to proceed against any person so committing perjury under the terms of this Act.

Sec. 3. That any purchaser who may purchase such original issue of security where material mis-statement is

made in the statement provided for under section 1 of this Act may recover twice the amount of all moneys paid for such original security and may join the issuing company and each of its officers, directors, and promoters as well as the underwriting syndicate, and each and every other party to the sale of such security; and judgment shall be rendered jointly and severally against each one thereof if and when material mis-statement is established; provided: That suit must be brought within one year after the purchaser shall have knowledge of such material mis-statement.

Sec. 4. That any person who shall mail or cause to be mailed in any post office of the United States any original issue security, knowing that the statement required by this section has not been filed as prescribed herein; or who shall mail or cause to be mailed in any post office of the United States any statement required by this section knowing the same to be false in any particular, shall be fined not less than \$5,000, or imprisoned not more than five years, or both such fine and imprisonment.

THE PLATINUM MARKET during the first quarter of 1919 was easier than in 1918, owing to the facts that the governmental restrictions on the use of platinum had been removed and that the Government was disposing of its surplus stocks. The low price of \$99 per ounce was reached late in March and was maintained about a month, but the price gradually stiffened until August, when the Government stocks were exhausted, and then abruptly rose to \$110 per ounce. Since the middle of August the price has continued to advance about \$5 each month, the demand for the metal has been strong and the supply short. During the first nine months of 1919 about 40,400 oz. of platinum was imported, and importation at this rate will probably be continued during the rest of the year, so that, if the normal domestic production of 7000 to 10,000 oz. is maintained, about 54,800 oz. of new platinum should be available, aside from the stocks of platinum, about 65,000 oz., held at the beginning of 1919. So far as known there has been little change in the domestic mining of platinum. The wide search made in 1918 for domestic sources of platinum has apparently yielded little results. Colombia may supply more crude platinum in 1920 than in the past, but its producing capacity is limited by the methods employed in washing the gravels from which the metal is obtained. Practically no supplies can be expected from Russia for several years. The osmiridium field of Tasmania appears to need only higher prices to stimulate larger production, but even with this stimulus it can probably produce not much more than 2000 oz. per year. According to James M. Hill, of the U. S. Geological Survey, there seems to be little hope of any marked increase in the output of platinum in the United States or Canada over the small output heretofore made, and as the supplies are below normal and the demand is large it is reasonably certain that the price of platinum metals in this country during 1920 will be at least as high as it was during the last quarter of 1919, and possibly higher.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ALASKA

TRANSPORTATION PLANNED FOR SALMON RIVER DISTRICT.

HYDER.—According to reports from Seattle, Governor Riggs of Alaska has left for the Eastern States with a view to interesting Government authorities in the question of supplying more adequate transportation facilities for Hyder. He is quoted as expressing confidence in the future of the Salmon River district to which general attention and interest has been attracted by the Premier mine. The Alaska Territorial Government, co-operating

ARIZONA

'SAFETY-FIRST' REWARDS FOR C. & A. EMPLOYEES.

DOUGLAS.—Little change was evident at the local smelters during the month, both the Copper Queen and Calumet & Arizona plants maintaining the scale of operations fixed two months ago. Three representatives of United Verde company were visitors at both smelters during the last week of January, in order to study the ore-crushing practice. From here they went to El Paso on a similar mission. This was preliminary to making final recom-

MIAMI, ARIZONA. MIAMI NO. 4. SHAFT IN BACKGROUND. POWER-PLANT AT EXTREME RIGHT

with the Forestry Service and the Alaska Road Commission, is to have a road completed up Salmon river, across American territory to the British Columbia border by next summer. It is well to mention here that the British Columbia government has expended a considerable sum in the construction of a road from Stewart to Hyder and in the building of a road from the American boundary to the mines. More expenditure, it is likely, will be authorized this year for the further improvement of means of transportation on the Canadian side. Governor Riggs is credited with saying that this American road will permit silver ore being brought to Hyder for transportation to the smelters. He also is said to be dissatisfied because the American steamship lines do not touch at Hyder while the vessels of the Grand Trunk Pacific Steamship Co. do so at regular intervals.

mentations upon the type of crusher to be adopted by the United Verde in its new 2500-ton plant which soon is to be erected. The Clark officials were C. M. Hoffman, superintendent of machinery; Thomas Taylor, superintendent of the smelter; and Charles Kuzell, assistant superintendent of the smelter.

BISBEE.—The annual safety-first meeting of the C. & A. company brought forth announcement that 16 of the company's 28 shift-bosses had made perfect records, each having worked the men under him 2500 shifts without a single man being laid off for injury. Each man received a substantial prize. Since inauguration of the safety movement in 1914 there has been a decrease of 57% in number of accidents. It is hoped to make 1920 the banner year in this respect. The men receiving prizes were R. B. Linden, J. F. Ward, George Graham, P. V. Banks,

Ted Dunlap, Tom Mason, J. C. Lackner, William Sharp, Norman McKenzie, and M. E. Kaum, of the Briggs mine; J. R. Wester, N. J. Cosgrove, John Saunders, W. D. Harrington, Tom Fuller, Jacob Erickson, M. K. McCrea, and George Matzeil, all of the Junction mine.

TUCSON.—J. H. Huntsman, president of the Gold Prince Mining Co., has denied that his company has offered \$500,000 for the purchase of the Dos Cabezas Gold Ridge mine as stated recently at Willecox by H. C. Kimball. The Gold Prince has been negotiating for the purchase of the Dos Cabezas mine but no definite offer for it has been made. The matter was brought up at a meeting of stockholders held in Willecox, early in January, and committees were named representing both companies to investigate and report upon the proposed sale or merger of the two properties, which adjoin in the Dos Cabezas district of Cochise county. A definite proposition will be made when a second joint meeting of stockholders is held at Willecox on March 4. The stock of both companies is held mainly by Arizonans. Favorable report has been received here relative to flotation-concentration tests made upon ore from the Daily-Arizona Consolidated Copper Co., operating in the Catalinas near here. Recovery of 93% of the copper was obtained from ores containing an average of 6% copper, besides gold, silver, and zinc. A body of 70,000 tons of ore averaging 3% copper and \$2 gold and silver, has been developed. Following construction of a road from Oracle to the mine, it is anticipated that a mill will be built.

COLORADO

MINING MEN CONVENE AT DENVER.

DENVER.—The Colorado chapter of the American Mining Congress and the Colorado Metal Mining Association recently concluded their estomary annual convention. The sessions continued three days and were held in the Senate Chamber of the Capitol. They were attended by many of the State's representative mining men such as George M. Taylor, Bulkeley Wells, George E. Collins, Charles A. Chase, R. M. Henderson, and Jesse F. McDonald, all of whom participated actively in the proceedings and discussions. Every mining county was well represented by delegates. Numerous papers were read upon such subjects as mine taxation, industrial insurance, complex-ore problems, and the development of the oil-shale industry.

A number of resolutions, after passing through a committee, were passed by the convention. One such resolution provided for the holding of a mining exposition in Denver's municipal auditorium during the coming summer. In the discussion of this resolution the idea was elaborated until, if the exposition be held as suggested, it will be most comprehensive and will include a pioneer placer camp along the bank of the Platte river within the city limits, displays of primitive devices along with up-to-date apparatus in all mining and milling lines, collections of rare and precious ores, a division for oil-shale, and demonstrations in ore-dressing and concentrating by gravity and flotation methods. George M. Taylor, presi-

dent, will appoint a committee to undertake full charge of this project.

One resolution urged investigation by Colorado's congressmen of the alleged extortionate prices charged by explosive manufacturers. An appeal to the U. S. Director General of Railroads and to the State Public Utilities Commission to abrogate a recent flat increase of 25% in freight-rates on ores was the substance of a resolution. Another protests against the proposed increase of 20% in the price of electric power by the Colorado Power Co., and calls upon the Public Utilities Commission to not grant the increase.

It was resolved that the Legislature should appropriate sufficient funds to enable the State Geological Survey to undertake more work in the mining and mineralized regions and that measures should be taken toward greater co-operation between the Federal and State bureaus of mines to the end of securing more investigation into the treatment of low-grade complex ores. The Jones-Reavis Senate Bill 2232, designed to unify all Federal engineering activities into a Department of Public Works, was favorably considered. Vigorous protest was raised against a proposed law being formulated by the county commissioners on the subject of mine taxation. The resolution stated that the passage of such a law would "result in a severe additional handicap to all mining operations and bring about the closing of the majority of the mines now producing."

To anyone familiar with former activities of these two organizations—the American Mining Congress and the Colorado Metal Mining Association—in combatting and denouncing the 'smelter trust' in Colorado, there is a tone of cynicism in one resolution which, after pointing out the sharp decline in the production of gold and silver during recent years and the closing down of two of the largest custom smelters, petitions the American Smelting & Refining Co. to delegate its president to make a visit to Colorado to look over the situation.

MICHIGAN

NO. 3 SHAFT AT THE CHAMPION MINE IS INOPERATIVE.—DEVELOPMENT WORK BY ARCADIAN CONSOLIDATED.

HOUGHTON.—Champion mine of the Copper Range is operating but three shafts. No. 3 shaft was discontinued last October and probably never will resume operations. All of the mineralized territory that was tapped by this shaft may be worked quite as economically from No. 2 and No. 4 shafts and the cost of maintenance of this additional shaft is thus eliminated. The abandonment of No. 3 was at the 21st level, at a depth of 2339 ft. from surface.

Sinking continues at No. 1 and at No. 2 shaft, a total of 200 ft. having been done at No. 1 during 1919, and 220 ft. at No. 2. No sinking was done at No. 4 last year. As a matter of fact, the Champion has more ore occurring in true fissures than the Trimountain or the Ahmeek, where the fissure veins have been a continuous contributor for many years. At this time No. 1 shaft has attained a total depth of 2714 ft., the 25th level; No. 2,

2700 ft., the 24th level; and No. 4 shaft is down 2388 ft., the 22nd level.

R. H. Shields, president of the Arcadian Consolidated, announces the complete success of his Eastern trip, from which he returned to Houghton last week. He has succeeded in attracting strong New York interests to the property and the company is now in a position to go ahead with development work for at least two years without likelihood of an assessment.

New Arcadian could resume operations today if market conditions warranted. As it is, the resumption of the development work probably will be delayed till March 1. Only a force sufficient to keep the water out of the New Arcadian shaft has been maintained. Since the suspension of operations the New Baltic shaft has filled, but as these workings are not extensive the cost of unwatering will be less than would have been the expense of keeping the shaft free from water.

NEVADA

REVIVAL OF ONCE-FAMOUS SILVER MINES.

RENO.—Mining in Nevada, as a result of higher metal prices, is being done on a larger scale and is on a better financial footing than for many years past. In every part of the State where metal has been found, old and new areas are being prospected, while recent discoveries have been made in several localities. A half dozen or more once-famous silver-producing camps show signs of returning vitality. Virginia City, Eureka, Austin, Tuscarora, Candelaria, Marietta, Montezuma, Cortez, and Unionville, all famous a generation or more ago, are again centres of activity. Many outright sales of mines and prospects have been recorded; many properties are being worked on a lease and option basis; and funds are being provided directly for mining. As a result, fewer automobiles are sold to brokers and promoters, but considerably more rock is broken and the powder and machinery salesmen are kept busy. The collapse of the Divide boom has been ascribed in large measure to the action of company promoters, in 'dumping' on the market their promotion stock before the treasures were financed.

At Virginia City the old bonanza properties are taking a new lease on life. Deep levels are being re-opened, virgin areas explored, and burned stopes reclaimed, resulting in a substantial increase in production. Annual reports on the Consolidated Virginia and Ophir mines, by Whitman Symmes, manager, describe mine improvements, new ore-reserves, augmented mill-capacity, and growth in net profits, with liquidation of old indebtedness. A number of the old mines are being worked, for the most part on a limited scale but with prospects of increasing production. Several properties lying in the belt between the Comstock and Brunswick lodes will be developed, actively, with the coming of settled weather conditions. More than 400 miners are said to be employed at present.

Eureka is staging the most pronounced revival among camps of the 'moribund' class. The Ruby Hill Develop-

ment Co., of which Edward O. Holter of New York is president, has acquired from the United States Smelting & Refining Co. a long term lease, with an option on the control of the Richmond Eureka property, at one time the largest silver-lead producer in this country. The mine was equipped with high power pumps and machinery several years ago when operated for a time by the U. S. Smelting Co. Shipment of fluxing ore to that company's smelters in Utah was interrupted by a railroad wash-out, and when the road was rebuilt a controversy over freight rates resulted in abandonment of the project. A railroad spur is being laid from the Eureka & Palisade narrow-gauge main track to the mine, on Ruby hill. Three deep shafts on the Richmond and Eureka Consolidated groups will be utilized in development work at depth. The Eureka-Croesus owns a group of mines that were notable producers of high-grade ore, with the famous old Dunderberg as the central property. A large amount of work has been done during the past year; rich orebodies have been opened far below the early levels, a valuable asset has been found in quantities of stopes-filling that is said to average above \$20 per ton; and avail-

THE CUMBERLAND MINE, NEAR MAYDAY, COLORADO, PARTLY BURIED IN SNOW

able reserves, including the old slag-pile, are appraised at many millions of dollars. Eugene Davis, the manager, has purchased the Eureka & Palisade railroad, and upon the advice of J. H. Mackenzie and George O. Bradley and others, will build a smelter in the spring. Julius Huebner, the superintendent, reports an average silver-lead content of \$23 per ton in filling drawn recently from the main Dunderberg stope. Sacked ore assaying \$400 per ton has been shipped lately to Utah smelters. The Eureka-Holly is sinking its main shaft from the 400-ft. point and a winze below that level is in high-grade ore. The richer ore is shipped to the smelter and 60,000 tons of mill-ore is blocked-out above the 400-ft. level. The Eureka-Climax is driving a tunnel to cut the Deadbroke vein below old stopes that produced rich ore. Work will be started on several other properties in the district with the coming of good weather.

At Candelaria the work of the Candelaria Mines Co. has been confined chiefly to the Lucky Hill mine, from which a considerable quantity of ore has been shipped in the past year. The company, now controlled by the In-

ternational Nickel interests, has options on three of the largest early-day producers and owns the Lucky Hill mine. Engineers report several hundred thousand tons of low-grade free-milling ore available on these properties. Charles D. Kaeding, manager, has been inspecting the property. Mr. Kaeding is manager, also, for the Dome Mines Co. and the Rochester Nevada Silver Mines Co. The Candelaria company is now planning the construction of a mill. Marietta, a short distance from Candelaria, was an important producer of silver in the 'seventies. Prospectors lately have found rich croppings, resulting in the location of a number of claims. One or more of the old mines will be re-opened shortly and worked on a substantial scale.

In Humboldt county, which lost most of its active mines when Pershing county was created, the camp of National is still sending out occasional shipments of high-grade ore, but only lessees are working. At Spring City, north of Paradise, an effort has been made to revive the old Bell silver mine, but it is reported that W. C. Ralston and associates have failed to make the payments required under the option. A discovery of some importance is reported at a point near the Adelaide copper property, south of Golconda. Near Inlay, a station on the S. P. railroad, the Majuba Hills company is said to be producing some good ore that contains a number of metals.

UTAH

DEVELOPMENT AT SILVER KING COALITION.—NEW PROPERTIES IN EUREKA DISTRICT.

PARK CITY.—Shipments for the week ending January 24 totalled 2344 tons, as compared with 2198 tons for the previous week; the increase being due to heavier shipments from the Ontario property. Details follow: Ontario, 811 tons; Judge Mining & Smelting, 654 tons; Silver King Coalition, 551 tons; Daly-West, 164 tons; Daly Mining, 110 tons; Nalldriver, 155 tons.

The new ore, recently found in the cross-cut from the drift on the 700-ft. level of the Nalldriver mine, continues to show consistent improvement, according to J. D. Fisher, superintendent. This vein averages 35 oz. silver and 30% lead, and has been drifted upon eight or ten feet. The cross-cut is being continued to explore the mineralization on the contact, which lies a short distance ahead.

The recent program of development at the Silver King Coalition property has opened a large and hitherto untouched ore-zone, according to W. Mont Ferry, the new managing director. Should expectations be realized, the development work will open up new territory in the ore-bearing formation for a distance of about 3000 ft. on its strike. The orebodies discovered in the Coalition have been found along the fissure system, which embraces the Gold Ledge, Jewel, and other fissures. These stopes were found in lime beddings overlying quartzite along north-east and south-west fissures. Paralleling these fissures to the north-west some large stopes, including what are known as the American and O'Brien stopes, were mined, but a fault was encountered which, for a long time, was

accepted as the end of the ore-zone in the paralleling fissure zone. The lime strata traversed by the two fissure systems were correlated and the faulting system encountered in the O'Brien stope was mapped out, after which development work was undertaken in the M. L. M. drift, a cross-cut tunnel which extends from the main shaft on the 1300-ft. level to the paralleling fissure system. The company is also pushing prospecting work in other parts of its property. In the old stopes and upper levels, it has adopted a leasing plan to clean up the ore which, on account of the excessive cost of supervision, could not be profitably mined on company account.

EUREKA.—The Iron King branch of the East Tintie railroad should be completed about February 10. This property has a large tonnage of iron ore blocked out, which is ideal for fluxing. As soon as the railroad is completed, shipments to valley smelters will begin. The recent surface-find at the Tintie Empire property has been opened up by trenching for a distance of 30 ft. along the vein, and for a depth of 4 or 5 ft. Theo. Nicholes, superintendent, states that recent assays of the ore show 7 oz. silver and 26% lead.

Work of sinking a new double-compartment shaft at the property of the Tintie Delmar company in the northern part of the district, has been started. Although this property was located a number of years ago, no work has been done on an extensive scale. Recently a reorganization was brought about and funds raised for extensive development.

Arrangements have been completed for the reorganization of the Black Warrior Mining Co., whose claims adjoin the property of the Bullion Beck mine. The Black Warrior company was launched many years ago, when a shaft was sunk to a depth of 300 ft., with a small amount of drifting, but in recent years it has been inactive. The company owns 32 acres of valuable mining ground, and has a capitalization of 250,000 shares with a par value of 50c. It is proposed to increase the number of shares to one million, and after the necessary funds have been raised, active development will be started, according to plans of Daniel Martin and William Hatfield, who own the control.

Organization of the Tintie Union Mining Co. to develop 496 acres of patented land in the East Tintie district, owned by W. C. Albertson of Salt Lake City, has been affected, and articles of incorporation filed with the Secretary of State. This property is in the vicinity of the Apex Standard, and is considered promising mining ground by engineers and geologists familiar with the district. Officers and directors of the new company are: W. C. Albertson, president and manager; George Haverkamp, vice president; C. Q. Albertson, vice-president; George G. Armstrong, secretary and treasurer; A. G. Burritt, J. C. McClain, and I. G. Albertson.

A good lead of ore which has been followed for some time on the 1640-ft. level of the Eureka Lilly is showing improvement, according to Grant H. Snyder, general manager. Samples of ore taken recently from the face of the drift show from 18 to 25% copper, 10 to 14 oz. silver, and from \$4.50 to \$14.60 gold per ton.

BRITISH COLUMBIA

SHIPMENTS TO SMELTER AT TRAIL.

VICTORIA.—It is announced that the Consolidated Mining & Smelting Co. of Canada has taken over the Jordan River properties on Vancouver Island, known as the Sun-loch group. These have been under development for some time, about 1000 ft. of cross-cutting and drifting and 500 ft. of diamond-drilling having been done. Besides this there has been constructed some 6000 ft. of automobile road. A four-drill compressor plant has been installed and new buildings erected. A track also has been laid from the mine to the waterfront.

STEWART.—Native silver is reported to have been discovered on the cross-cut being driven on the E. Pluribus claim by William Noble, superintendent of the develop-

TRAIL.—Additions as well as some remodeling are under way at the Trail smelter of the Consolidated Mining & Smelting Co. An additional drafting office is being provided for the use of a staff of about twelve draftsmen who will be engaged in connection with the new concentrating plant which will probably be erected at Rossland. The site of the mill has not been definitely decided as yet, there still being a possibility that it will be placed at Trail, owing to the difficulty in obtaining a satisfactory water supply at Rossland. Sixteen properties shipped ore or concentrate to the Trail smelter during the week ending January 14, the total being 6540 tons. Included in these were three of the Clarence Cunningham properties, the Queen Bess, at Three Forks, and the Wonderful and Richmond-Eureka, at Sandon. For the first two

PRECIPITATING COPPER ON SCRAP-IRON AT THE LEACHING-PLANT OF THE UTAH COPPER CO., AT GARFIELD

ment work in progress. The Big Missouri group, to which this claim belongs, has been considered to be an immense low-grade proposition but recent work has disclosed ore reported to contain silver in unusual quantity.

KIMBERLEY.—A shoot of silver-lead ore, samples from which have assayed between \$101 and \$103, has been discovered by Robert B. Durrant while tunneling on a gold-bearing quartz vein on Perry creek. This galena orebody in a quartz lode is only one feature of the property and Durrant proposes sinking to 120 ft. to ascertain whether the orebody persists and, if so, to gain stoping ground.

SLOCAN.—The Silver Bell is reported to be showing up satisfactorily on further development. A new find is announced as a result of a raise from the lower tunnel. It consists of 12 in. of mixed ore, through which more or less clean ore is scattered. The indications become better as the work progresses. The Silver Bell has about 1000 ft. of work in its two tunnels and raise, the latter cutting ore about midway between the tunnels.

weeks of the year a grand total of 12,214 tons has been shipped to the smelter, which is considered an excellent start.

ONTARIO

CYANIDE PLANTS AT PORCUPINE EXEMPT FROM ASSESSMENT.

PORCUPINE.—An important decision has been made by the Ontario Railway and Municipal Board in a test case as to the municipal taxation of mine buildings. Under the Ontario Assessment Act mine buildings, including concentrators and stamp-mills, are exempt from assessment. It was claimed by the township of Tisdale in the Porcupine area that cyanide plants did not come under the head of concentrators, and were consequently assessable for taxation. This claim was resisted by the owners of the Dome, Davidson, McIntyre, and other gold mines, and after going through several stages of litigation the case was finally decided in favor of the companies. Good progress is being made in development at the Clifton Porcupine, where some high-grade ore has been en-

countered at the 200-ft. level. A substantial tonnage of commercial ore has been developed on the 100-ft. level, and lateral work is being done on the 200-ft. level to determine the extent of the downward continuation of the vein. At the Gold Centre exploration by diamond-drilling is being undertaken. So far no outcrops have been found on the surface, which is heavily overburdened. A new mill with a capacity of 250 tons per day is planned for the Davidson. Labor is becoming more plentiful enabling the Hollinger and Dome to increase their working forces.

CORALT.—Litigation over the Bailey mine, which has been in progress for six years, has been terminated by the decision of the Appeal Court directing the liquidators to complete the sale of the property to A. J. Young. A new company will be formed to take over both the Bailey mine and the Northern customs concentrator. The La Rose Consolidated has started cross-cutting on the 155-ft. level of the University property to tap two veins cut at the 100-ft. level which showed high-grade ore in places. A recent sale of 400,000 shares of Peterson Lake stock puts the company in a position to carry on an extensive exploration campaign. The workings of the Seneca-Superior and Gould properties have been devatered and underground work started. Low-grade rock from the Seneca-Superior dumps is being profitably treated. The Waldman is now being operated by L. C. Campbell and associates of Montreal. At the Chambers-Ferland a substantial amount of low-grade ore is being developed in the No. 4 workings. A cross-cut is being run through that part of the property lying between the Nipissing and the La Rose, where some small stringers have been encountered. The tailing pile which has been optioned to H. Cecil and associates for \$55,000, is now being sampled.

GOWGANDA.—The McAlpine and Rawhide properties, situated about one mile north-east of the R. C. 101 claim of the Trethewey, have been taken over by a Toronto syndicate under the terms of an option. John J. Byrne is in charge and camp buildings are being built prior to the erection of mining equipment, now on the way. Several good veins have been uncovered on both properties, on each of which a shaft is down 100 ft. For the present, operations will be concentrated on the McAlpine where the shaft will be deepened. The North Cliff, a new company financed by Rochester capital, has taken over a group of claims $1\frac{1}{2}$ miles west of Gowganda township and begun active development. An adit will be driven into a high ridge where a series of veins have been uncovered on the surface. Norman F. Dye has been appointed superintendent.

KIRKLAND LAKE.—The annual statement of the Lake Shore company shows a deficit of over \$47,000 due to the strike. Mill heads averaged just below \$25, and production, below \$300,000. The net profits were \$38,273, and \$100,000 was paid in dividends. During December 975 tons of ore was treated with a production of 14,637.

TORONTO.—A merger has been effected of three prominent asbestos mines in Quebec province, owned by the Jacobs, the Federal, and the Berlin asbestos-mining companies. The new company under the name Con-

solidated Asbestos, Ltd., has a capitalization of \$10,000,000, of which stock for \$5,000,000 is issued, leaving \$5,000,000 in the treasury. The Jacobs mine is located at Thedford, and the Federal and Berlin mines at Robinsonville. Sir John W. Carson, who becomes president and managing director, is one of the most prominent mining men of Canada and largely interested in Northern Ontario enterprises, being president of the Crown Reserve and Porcupine Crown companies.

The twenty-second annual general meeting of the Canadian Mining Institute will be held at the King Edward hotel, Toronto, on Monday, Tuesday, and Wednesday, March 8, 9, and 10.

SONORA

DEAL PENDING FOR SALE OF CANARIO COPPER CO.

NACAZARI.—The Canario Copper Co., whose property is situated at the apex of a triangle, at a point five miles north-west of Pílares de Nacozari, and five miles south-west of the town of Nacozari, is believed to have proved the existence of a large hitherto undeveloped mineral belt lying between the Pílares orebodies and the Lily-Segundo of the Canario. The orebody on the 300-ft. level had previously been proved to be 100 ft. in width, with the grade of ore improving constantly. The cross-cut had to be abandoned temporarily owing to the flooding of the working by a large chamber of water, lying just beyond the foot-wall. The existence of this body of water was known and workmen had been warned against puncturing the tale foot-wall. However, one of the Mexican miners, overcome by curiosity, drove a bar through it and pried away a section. He and a companion working in the drift had a narrow escape from drowning in the deluge that ensued. For two weeks bailing and pumping at top speed had to be done before the 300-ft. drift could be entered again. Since that time the west drift has followed the same orebody, proving it to be at least 400 ft. in width. A party including George F. Shurtliff, consulting engineer with Cameron, Michel & Co., G. Henry Stetson, of the Stetson Hat Co., Stephen B. Bourne, former secretary of the Emergency Fleet Corporation, and Charles D. Donning, a mining engineer of Prescott, Arizona, visited the property and inspected the mine. The Nacozari Consolidated, on the other side of the Pílares mine of the Moctezuma Copper Co., has started three cross-cuts in its main tunnel, which is in the Pílares mineral zone. Two of these are being driven along the orebody. The third is driving toward another contact. The company recently began using mule trains for handling waste and ore in the main tunnel, each mule drawing a train of five cars.

PÍLARES DE TERAS.—A deal involving the sale of the Cinco de Mayo mine to an American syndicate is reported to be pending. The price is said to be \$500,000. The mine is reputed to be one of the richest silver properties in northern Sonora, and was operated under government management for a time, but unscientific methods, combined with notorious grafting on the part of some employees, created a loss that resulted in shutting down.

ARIZONA

Ajo.—Notwithstanding production was curtailed last year to a bare 60% capacity, due to the abnormal conditions obtaining in the metal market, the New Cornelia Copper Co. produced copper at a cost of 13c. per pound. This figure is exclusive of a reserve for ore depletion and excess-profits taxes. The company produced approximately 40,000,000 lb. of copper in 1919, or about 8,000,000 lb. less than in the preceding year. New Cornelia has been a commercial producer only since the middle of June, two years ago. Beyond the construction of its 500-ton experimental flotation plant, New Cornelia was not obliged to do any building or plant-enlarging last year. Experiments thus far with the flotation process have been satisfactory and the company will probably take a definite step in the direction of using the system in the not distant future.

Mayer.—Copper mountain has another shipper which has come into this class within the past few weeks. It is the Franco American company's mine which is situated about one and a half miles north-east of the Arizona Birmingham. Fred Bowler, of Prescott, took over this old property during last year and organized the company. Former owners shipped four carloads of high-grade copper, the lowest car averaging 22% and the highest 35% copper and about \$10 in gold and silver. The mine, when taken over by the present company, had been developed by an incline shaft 250 ft. deep with levels on the 125 and lowest stations. The mine is now being developed on an extensive plan. New equipment has been installed at the shaft for deep sinking, the plan being to put the work down to the 1000-ft. level. There are several carloads of high-grade ore on the dump ready for shipment and as soon as the new truck road is completed to the mine one or two carloads per week will be shipped from Dewey.

CALIFORNIA

Corning.—Clarence Wolf and J. D. Overstreet report the discovery of copper-silver-gold ore in the mountains west of Corning. Prospecting has been carried on for several months and a strong orebody is said to be exposed.

Nevada County.—W. A. Stutsman of Los Angeles is at Meadow Lake inspecting the Excelsior mine with a view to its purchase. The property is owned by Peter Bokay.—The water in the old Idaho-Maryland shaft is now below the 600-ft. level and is being lowered rapidly. Between the 200 and 400-ft. levels the shaft was found to be in a bad condition and a large amount of re-timbering was found necessary. No mining of consequence will be attempted until the 1000-ft. shaft is unwatered.—The county recorder filed 1077 exemption-claim notices for 1919.

Placer County.—The Rising Sun mine near Colfax is being re-opened by a company headed by John Zeeman of San Francisco and Messrs. Russell, Loebner, Gray, and Klinker of Colfax. The mine is unwatered below the 500-ft. level, two 50-hp. electrically-driven centrifugal pumps being used for that purpose. The four-compartment shaft is 800 ft. deep. The mine closed in the early 'eighties due to litigation. The Rising Sun has a production record of over two million in gold. The company has applied for permission

to sell 50,000 shares of treasury stock for the purpose of building a mill and exploring the mine.

Taylorville. Trask & Coffey Co. has resumed operations following the receipt of machinery and improvement in the labor situation. The management plans work on a larger scale and reports a deposit of rich copper ore. Diamond drills are reported to have exposed a 7-ft. vein of 32% copper ore in the Walker mine, controlled by the Anaconda Copper Co.—Driving of the cross cut from 400-ft. level of Grass mine is proceeding rapidly and the orebody should be intersected shortly. An eight-drill compressor has been added to equipment; 22 men are employed under the management of W. J. Gruss.

COLORADO

Cripple Creek.—Royalties aggregating \$60,326 were paid the United Gold Mines Co. from ore shipments by lessees, during the last fiscal year, according to the report mailed to stockholders, along with their dividend checks; \$40,000 was disbursed at the rate of 1c. per share.—An electric motor has recently been installed at the old Victor mine on Bull Cliffs, by the Komat Leasing Co., a local organization operating the property and the Arvilla group adjoining. The Victor is controlled by the Smith-Moffat Mines Co.—An additional electric compressor of 10-drill capacity has been added to the equipment at the No. 2 shaft of the Modoc Consolidated company, preparatory to development of the Combination claim, north-west of the Last Dollar mine, on which the No. 2 shaft is situated.

IDAHO

Coeur d'Alene.—The Big Creek section, commonly known as the 'dry ore belt', is attracting attention on account of the unusual amount of work now under way, and by reason of several recent transactions involving properties in the locality.—As a result of consolidation of the Big Creek Leasing Co., holding a lease on the Yankee Boy mine, with the Big Creek Silver Mining Co., active work has now started in the Yankee Boy lower levels.—Adjoining the Yankee Boy lies the property of the Yankee Girl Mining Co., now under bond to E. C. Tonsley of Spokane. It is stated that work will soon be under way on this property.—The Sterling Silver Mountain company has surface showings said to indicate exceptional values in silver in a 20-ft. vein, which will be reached at a depth of 300 ft. by the present cross-cut.—Another effort is to be made to find orebodies in the National mine, above Mullan. Operations are to be resumed as soon as a crew can be secured.—The Star Creek Mining Co. will ship a 50-ton car of crude ore to the Bunker Hill smelter at Kellogg, as soon as the work of loading has been completed. The ore will assay approximately 65% in lead, with about 8 oz. of silver per ton, it is said.—The Federal Mining & Smelting Co. has obtained admission to the workings of the Hecla Mining Co. at Burke, and its engineers are engaged upon a survey.—The Ajax Mining Co., operating at Burke, has found ore in that part of its property adjoining the Hercules, according to an official. This is at a depth of 750 ft. and at a point 650 to 700 ft. east of the line that divides the Ajax and the Hercules.

RESOLUTION UNANIMOUSLY ADOPTED BY THE JOINT COUNCIL OF ENGINEERS OF SAN FRANCISCO, JANUARY 13, 1920

Whereas, There is at this time a strong and wide-spread sentiment for Herbert C. Hoover for President of the United States as an independent candidate, free from political deals and pre-election pledges; and

Whereas, Mr. Hoover, by his work in Europe, has shown executive and administrative abilities of the highest order, particularly fitting him for handling both the economic problems of reconstruction at home, and our relations with other nations; and

Whereas, The Joint Council of Engineers of San Francisco has a patriotic duty to perform at this time, not only as representing Engineers, but also as a representative body of American citizens; be it therefore

Resolved, That the Joint Council of Engineers of San Francisco, representing 2000 Engineers in the Bay district, endorses Herbert C. Hoover for President and invites the engineering bodies of the United States to join with it in forming an organization to further Mr. Hoover's election, and in such other activities as will insure the affairs of the Nation being handled on an efficient and non-partisan basis, and be it further

Resolved, That copies of this resolution be sent to all engineering organizations and technical journals throughout the United States, and that such other steps be taken as will further the movement of "Hoover for President".

OBITUARY

John H. McChrystal, 57 years of age, one of the most widely known mining men of Utah, died at his home in Eureka, Utah, on January 27. Pneumonia was the cause of his death. He was manager of the Gemini Mining Co., the Ridge & Valley Mining Co., and the Godiva Mining Co., all in the Tintic mining district. He was a native of Franklin, Michigan, and came to Utah in 1875. Early in life he entered the mining business, in which he achieved considerable success. He was a member of the American Institute of Mining & Metallurgical Engineers. He is survived by a wife, two daughters, and one son.

Darsie C. Bard died of pneumonia at Butte on January 23. He was taken ill while underground in connection with the Elm Orlu litigation. He was born in 1878 and graduated from Harvard in 1904. Shortly after he went to Butte and became a member of the geological staff of the Anaconda Copper Co. In 1909 he was appointed professor of geology in the Montana State School of Mines, retaining this position until 1916, when he became consulting engineer to the Chicago, Milwaukee & St. Paul Railroad company. In 1917 he joined the staff of the British Columbia Smelting Co., with headquarters at Seattle. He contributed to the technical press and played a generous part in all professional activities.

Kurnal R. Babbitt, widely known corporation attorney, died at his home in New York City on January 23, at the age of 56. For a number of years past, he was general counsel of the various mining and railway companies which are under the general direction of D. C. Jackling, including the Utah Copper Co., Ray Consolidated Copper Co., Chino Copper Co., Nevada Consolidated Copper Co., and Butte & Superior Mining Co. He began the practice of law at Aspen, Colorado, in 1891, and later opened law offices at Cripple Creek, where he became acquainted with C. M. MacNeill, now president of the Utah Copper Co. When the Utah Copper Co. was organized in 1903, Judge Babbitt became associated with it as general counsel. In 1908 he moved his offices to New York City. Funeral services were held at New York City on January 26 at 3:30 p.m. Operations were suspended for five minutes, beginning at that time, at all of the Jackling properties in the United States.

Personal

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

W. L. Zeigler, of Seattle, has gone to Latouche, Alaska.

Leverett Davis, of Denver, was in San Francisco last week.

A. J. Taylor, of Vancouver, was in San Francisco last week.

E. P. Mathewson is now at Vancouver, B. C., and will be in San Francisco shortly.

Charles W. Goodale was here last week to meet his brother William Goodale.

Albert Burch has returned from a journey to Alaska. He is now at Oatman, Arizona.

Philip Argall will sail from Vancouver to Sydney by the 'Niagara' on or about February 15.

F. K. Brunton has recently taken charge of the La Prieta mill near Cullacian, in Sinaloa, Mexico.

L. S. Cates, with **D. D. Moffat**, made a tour of inspection of the Ray Con. Copper Co.'s properties in Arizona.

L. F. S. Holland is examining mines in Colorado, and expects to return to Los Angeles about the middle of February.

George C. Riser, superintendent of the Nevada Con. Copper Co.'s concentrator at McGill, was at Salt Lake City recently.

Richard A. Parker has been re-elected chairman of the mining bureau of the Civic and Commercial Association, at Denver, Colorado.

R. W. Mumford is chemical engineer in charge of development at the American Trona Corporation plant at Searles Lake, California.

Raymond Fennell, a director of the Central Mining & Investment Co., London, has been visiting mines and metallurgical plants in Utah recently.

H. S. Enlaw has been appointed general manager for the American Trona Corporation in California, and **Frederick Vieweg** the assistant general manager.

Paul Paine has severed his connection with the Gypsy Oil Co. to engage in the examination and appraisal of oil-lands. His address will be Box 1008, Tulsa, Oklahoma.

Vernon S. Rood, manager for the Utah Apex Mining Co., was married on February 3 in San Francisco to Miss Josephine Lindley, the daughter of Judge Curtis H. Lindley.

H. W. Morse has resigned from the position of technical manager for the American Trona Corporation and accepted the position of consulting physical chemist to the same company.

G. W. Miller has returned to Los Angeles from the Vulture mining district in Arizona, where he has been examining the United Grande Mines Co.'s property near Hot Springs Junction.

J. A. L. Gallard, who was mining editor of the 'Financial Times' for 18 years, has joined the staff of the 'Mining Magazine', as associate editor, and will take up his duties in February.

C. R. Olson, formerly mill-superintendent for the Como Consolidated Mines Co., has resigned to accept a similar position with the Kansas City-Nevada Consolidated Mines Co., at Bruner, Nevada.

H. Sato, mining engineer, of Tokyo, Japan, is in Utah, visiting mining and metallurgical plants. During the past six months he has seen all of the large mining camps in Canada and the United States, and is now on his way home.

THE METAL MARKET

METAL PRICES

San Francisco, February 3

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	12.00
Copper, electrolytic, cents per pound.....	19.25
Lead, pig, cents per pound.....	8 75-9.50
Platinum, pure, per ounce.....	\$135
Platinum, 10% iridium, per ounce.....	\$180
Quicksilver, per flask of 75 lb.....	\$80
Spelter, cents per pound.....	11.00
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

February 2.—Copper is inactive and steady. Lead is dull but firm. Zinc is quiet and easier.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 16.65 pence per ounce (.925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

Bankers are looking with a good deal of interest upon the movement, which appears to be growing, of floating below interest foreign securities in this market through issuing "American shares" secured by deposit here of certain foreign shares. This is regarded as offering the most potent remedy, ultimately, for the foreign-exchange situation. Present movement is the more significant because it is spontaneous and not induced by artificial measures to relieve the situation.

It has been pointed out that the present position of sterling and the other important exchanges can be remedied only by a flow of capital from the United States to Europe. Extensions of loans and credits only postpone the day of final settlement. With Europe in need of continued large supplies of our raw material and heavy indebtedness to this country for money borrowed, the credit balance against Europe will remain heavy for a long time to come, and this balance will consequently be reflected in a depreciation of foreign exchanges in this market.

But this depreciation of the foreign exchanges is not without its benefit to the European countries. Prevailing discount is an inducement for investment of American capital abroad. Movement means the salvation of security values on the other side, where, on account of the huge sums of government war loans, security markets are saturated beyond the investment demand. Particularly is this situation beneficial to Great Britain, and so far movement of foreign securities here since the War has been confined for the most part to the offering of British industrial securities. The position of sterling and reputation of certain British industrial have made a strong appeal to American investors.

The innovation of offering "American shares" against foreign stock as collateral really came when the War was in progress, when, in December 1916, 222,000 "American shares" were issued against 71,000 sub-shares of 7400 full shares of Royal Dutch Co. stock deposited in New York. But this operation did not present the same opportunities for profit on the exchange as have since appeared with the British issues floated since the termination of hostilities. Consequently a good many of the "American shares" have since been bought up by Dutch interests and the amount of Royal Dutch shares here considerably reduced. Early last summer 277,000 "American shares," each representing two original shares of Shell Transport & Trading Co. were offered in this market. A short while ago, 90,000 "American shares," each representing 2 1/2 original shares of Rand Mines, Ltd., were sold here.

Bankers believe this movement will become more extensive as time goes on. Listing of foreign securities on our exchange as a means of inducing the flow of American capital abroad is advocated. Bankers point out that this is the reversal of what happened subsequent to our civil War when the European capital flowed to this side to finance the railroad expansion of the United States and "American rails" became a feature on the London Stock Exchange. Offering of foreign securities in this market in the coming years, it is believed, will make a considerable part of European industries indebted to American investors.

Foreign exchange quotations on February 3 are as follows:		
Sterling, dollars:	Cable	3.37
	Demand	3.36
Francs, cents:	Cable	2.30 1/2
	Demand	2.30
Lire, cents:	Cable	7.11
	Demand	6.96
Marks, cents:	Cable	1.18

Eastern Metal Market

New York, January 28.

The markets continue generally quiet, with demand light in most of them. Prices are firm to easy.

Copper demand is fair and prices are steady.

The tin market has been quiet and sales have been light.

Demand for lead is decidedly lighter but prices are strong.

Prices for zinc are a little lower and demand is less. There is some price-cutting.

The antimony market is strong and advancing.

IRON AND STEEL

The pig-iron market has turned active. Prices having advanced to \$40, Valley, for basic, \$41 for Bessemer, and \$40, Birmingham, for No. 2 foundry. Furnaces are willing to sell and buyers have not hesitated to contract for large quantities even over the second half. Because of higher ore, coke, and freight rates, the cost of making iron is likely to advance in the near future.

The surprise of the week has been the eleventh hour decision of the Railroad Administration to secure maximum delivery of rails the coming month. Falling back on the technicality that we are still at war, orders of the war-time type have been issued on all rail-mills for a tonnage which will probably keep them busy for several months. The statement of earnings for the fourth quarter, made public today by the Steel Corporation, was a surprise, the net profit being far ahead of expectation. It is about \$35,000,000 against the most optimistic estimates of \$31,000,000.

COPPER

A better inquiry is reported than last week but the market is generally quiet. Producers or first hands continue to ask not less than 19.25c., New York, for electrolytic and 19.50c. for Lake for early delivery. It is reported that second hands are offering electrolytic as low as 18.75c., New York, for early delivery, due to the fact that they must close their accounts against deliveries of the metal. It is believed that the supply from this source is small. The tone of the market is strong and a better market is predicted by some for the near future. Because of the weakness in exchange values exporters are not pressing the market. Copper exports for 1919 are estimated at 226,611 gross tons against 328,844 tons in 1918 and 493,256 tons in 1917, the largest in the last five years.

TIN

The week has been a quiet one. Only light sales are recorded and at a lower level, due to some extent to the slump in exchange. The possibility that banks are calling loans is suggested as one cause of the selling, holders of the metal desiring to cash in. It has been a slow market. On Monday there was a little inquiry with the market easy, future shipment from the East being offered at 63.25c. and spot shipment at 62.75c. with bids reported at 62.50c. Because of record low levels in exchange yesterday, spot Straits was quoted as low as 62.25c., New York. Arrivals for the month have been 3855 tons, of which 610 tons came in at Pacific ports. Tin afloat is reported as 5155 tons. The London market yesterday was £293 per ton, an advance of £7 per ton during the week.

LEAD

This market has become decidedly quiet and there is little or no demand. In a very few quarters some disposition to sell is in evidence and prompt lead is offered as low as 8.45c., St. Louis. Lower bids, perhaps 8.25 to 8.37c., would result in business. Prompt lead, which was almost

unobtainable at 9c., New York, a few weeks ago, is now quoted at 8.75c., New York. The general market for early delivery is 8.45c., St. Louis, or 8.75c., New York, with the American Smelting & Refining Co.'s quotation unchanged at 8.25c., St. Louis, or 8.50c., New York.

ZINC

Most of the large producers are well sold up through the first quarter and are not forcing the market. Inquiry from galvanizers has been good, particularly for early delivery, and these needs have been taken care of in most cases. These producers are generally quoting prime Western at 9.10c., St. Louis, or 9.45c., New York, for early delivery. There is one large broker, however, who is offering at 9 to 9.10c. for early delivery, but says business is difficult to get. The fluctuations and lower levels in exchange have had their effect so that the slight reaction now prevailing is not a surprise. The lower exchange rate has been partly offset with slightly higher prices in London. Some of the labor troubles in the West have been adjusted.

ANTIMONY

The market is much stronger. Wholesale lots, five tons and more, are quoted at 11.25c., New York, duty paid, for early delivery, and the metal is scarce.

ALUMINUM

There is no change. Quotations for early delivery of wholesale lots are unchanged at 31.50 to 32.25c., New York.

ORES

Tungsten: The market is absolutely inactive, awaiting possible action of the Senate on the tariff question. Some expect a decision this week. Chinese ore is offered as low as \$6 per unit and the range on other grades is up to \$15 per unit. Quotations are nominal, sellers being inclined to hold their supplies which would increase in value with the passage of a tariff. Ferro-tungsten is nominal at around \$1 to \$1.15 per lb. of contained metal.

Molybdenum: Quotations are unchanged at 75c. per lb. of MoS₂ in 90% concentrates. The market is dead.

Manganese: As high as 80c. per unit has been paid for foreign ore. The market is strong and ores are scarce.

Manganese-Iron Alloys: The markets for both ferro-manganese and spiegeleisen are very strong. For the latter a maximum of \$57.50, furnace, is now asked and sales of several hundred tons have been made at \$55. For export 500 tons has gone to Belgium and 1000 tons to Holland, the price for the latter having been \$58.25. Sales of about 1000 tons of ferro-manganese from a recent new producer are reported at \$150 to \$160, delivered, for delivery to July 1. For last half domestic makers are talking \$160, delivered. For the present they are out of the market. One representative of a British producer has 2000 to 3000 tons for delivery during May or later at \$145, seaboard, and another has 500 tons held at \$150, seaboard.

Some chrome ore, according to Charles Hardy, Inc., Park Row building, New York, has been offered for shipment from abroad, but almost invariably business has been held up for want of arranging satisfactory freight. Indian chrome ore now on the way to the United States is offered at 75c. per unit for material running about 50%. At this figure further quantities can no doubt be contracted for. The same firm gives a nominal quotation for quicksilver at \$93 per flask, adding that it has, however, been possible to buy at a considerable concession from this figure.

TRADE with our excellent neighbors and customers, the Canadians, is suffering from a discount of 17% on their dollar. Is it not time to repeal the embargo on the exportation of paper pulp from across the line? We need it greatly, as abnormal prices and unrestricted profiteering indicate so uncomfortably. Why does the Canadian government hesitate to do the obvious?

FOOD-DRAFTS are being sold as a means of affording Europeans in this country a convenient and safe way of aiding their friends in the war-devastated countries. This method has the advantage of being operated without coming within the incidence of taxation or necessitating large credits. The burden of these drafts will be borne by the three or four million of our population that retain family ties in Europe. The money used in purchasing food-drafts would otherwise be remitted to Europe either by money-draft or in paper currency, and would be of little use so far as the purchase of food is concerned, because there is none available outside that controlled by the governments and the supplies of the American Relief Administration. All other food is subject to requisition. This information should be given to alien laborers at mines and mills. Write to the office of the Relief Administration at 115 Broadway, New York. Mr. Herbert Hoover is chairman and Mr. Edgar Rickard is acting as secretary.

HEARST and his yellow journals are advocating a new party with the slogan 'Hearst first', in order to save the country from the bold bad men who do not appreciate him and his trickeries. That might be a good idea, if only we could have another party headed by Herbert Hoover. The two men could stand for opposing ideas, which is more than can be said now for the politicians of the two old parties. The frothy provincialism of the man who has befouled American journalism would afford a fine contrast to the intelligent humanism of the man who has proved his extraordinary administrative ability in great works of beneficence, both abroad and at home. However, as Mr. Hoover suggests, two parties is enough; the old ones are still in evidence. We publish a statement from Mr. Hoover on page 246. It speaks for itself; it is sane and sagacious. He says clearly that he is neither a reactionary nor a radical; he stands for orderly progress in national affairs; also for the League of Nations, with minor reservations. He waits for the national parties to declare their platform; until then he cannot commit him-

self further. Why should he? Meanwhile we venture to suggest another reason for reticence on his part, he is acting chairman of the Industrial Conference, which is a non-partisan body engaged in work of the highest importance.

SENATOR SMOOT has been denouncing the waste of print-paper by the executive departments of the Federal government; he deplors the cost of printing and distributing the speeches of Mr. McAdoo and other Cabinet officers during the War. Here we detect a jaundiced eye; many of those speeches served a distinctly useful purpose in arousing national sentiment; even a Republican might concede that. The wastage is not all there; it extends to Congress itself, notably the 'Congressional Record' and the re-printing of speeches delivered by honorable senators. No sign of economy is evident. All the scribbling paper we use is supplied by Government departments, which send us daily multi-graphed circulars that are typed on one side, leaving the other for what, to us, seems a better service. We hear about the price of paper, which is exorbitant and prohibitive, but we hear too little about the waste of it by officials and newspapers all over the country.

LAST week we discussed various efforts, by means of State and Federal legislation, to prevent fraudulent promotion. We note how the law is being evaded by selling, not shares in a company, but other units conferring participation in speculative projects. For example, the New York Brokerage Co. of Shreveport, Louisiana, offers to sell an 'oil lease'. A remittance of \$100 sent to the San Francisco office of this company—which has borrowed the name of New York—will buy a six-acre lease near New Homer, in Louisiana. The lease will be made out in the remitter's name and will be recorded in the Recorder's office, without further charge. The advertisement says that these are "commercial leases and run from three to five years with option of renewal by payment of one dollar or so per acre". The language seems studiously vague, except as to urgency; if one wants to make money quickly, one must hurry, says the advertisement. "There is no time to 'take the matter under consideration'. It is men of quick action, men who do things [and people] as the late Jay Gould did them, 'right now', who make the big profits in oil." Therefore, concludes this impudent scoundrel, "Send along your order before you lay this paper down". The same

Irresponsible newspaper prints several similar advertisements. One is headed, "Millionaires Made Over Night!" This one invites correspondence, offering to show how the "syndicate plan" will ensure a fortune to the simpleton who invests in "our leases". A third offers 9-year leases at \$10 per acre, sold in 10-acre tracts or more. "These leases are all drawn up legally on regular Form Commercial lease, same as big Companies use." A fourth invites the gullible to "send in your check or money order for \$100 to cover what you can afford to buy at \$12 per acre, either two and one-half or ten acres. I'll send you a legal assignment of the same ready to be mailed for recording, a large map of Texas, showing the location of the property and its proximity to producing and drilling wells, together with a copy of the official plat of the subdivision with your tract number and location plainly marked." Why not send a pound of tea also? A fifth spieler offers "a 1-acre oil lease in surveys 351 or 352 for only \$15.00; or a 5-acre oil lease for \$65.00. This price will surely advance next week and then you may be sorry if you don't buy now." We quote verbatim. This sort of thing is outside the scope of any existing blue-sky laws, because no shares or bonds are offered. Apparently there is need for a law that will take cognizance of such methods.

IT is interesting to observe that at a recent Safety-First convention, the Calumet & Arizona company at Bisbee was able to award prizes to 16 of its 28 underground shift-bosses for attaining a perfect record in respect to such injuries as incapacitated men working under their immediate direction. This record covered the year 1919, and applies only to bosses with a minimum of 2500 shifts to their credit. The company also announces that during the year there was a decrease of 57% in the number of accidents as compared with 1914. At another large property a decrease from 4.2 to 1.8 disabling injuries per 10,000 shifts worked is attributed directly to the introduction of an efficient safety organization. These are typical of scores of mines where remarkable results are credited to the Safety-First movement. Underground mining operations entail an inherent and undeniable element of hazard, over and above that to which workmen in many other industries are exposed. The work is necessarily done in artificial light, and much of it even in an inferior kind of artificial light, owing to the impracticability of distributing electric current outside the main levels. Moreover, operations always resemble construction work in that the miners are continually engaged on temporary floors, with danger lurking above their heads as well as at their feet. Daily travel through a shaft in an open cage and the continual handling of high explosives are features characteristic of the occupation of the miner. The attitude of most mining companies ten or fifteen years ago was to recognize the distinctive dangers of the industry and accept as inescapable a high proportion of accidents resulting in injury and even death; now the danger is recognized as before, but the effect is rather to emphasize the need for more than ordinary application of safety methods

and teachings. It is a fact that the accident records in plants for the manufacture of dynamite and other high explosives are notably low, although it can scarcely be maintained that the element of risk is not extraordinary. The explanation is simple. Because the hazard is clearly recognized, the necessary precautions are taken and safety rules are observed as a matter of course. This idea is the basis for safety propaganda in mining. There are two distinct phases of the work: the first includes the planning of operations so that they can be performed in a safe way; the selection of equipment of approved design; the provision of mechanical safeguards; the posting of rules and of directing-signs; and similar precautions, which involve, principally, the outlay of money. The more difficult part of an effective program is that of educating the workers themselves. Miners are prone to be careless, more so perhaps than men engaged in other occupations. Some are inclined to look with a kind of contempt at warnings; some conclude that the measures taken by the company are so elaborate as to eliminate danger, and therefore make individual care superfluous. However this may be, the recognized problem is to get co-operation and to educate each miner so that he instinctively and habitually does his work in the way that is safe for him, safe for the man working with him or under his direction, and safe for the man who next may be engaged on the same job or in the same vicinity. Originally a slogan, 'safety first' has become an institution, and every progressive mining company sees in it not only a source of financial gain but a humanitarian movement for the preservation of life and health. It is one ground at least on which capital and labor can meet with mutual goodwill.

WE have received further, semi-official, information concerning the Premier mine, in the Salmon River district of British Columbia. It appears that last October an examination of the mine was made by Mr. H. A. Guess and other engineers of the American Smelting & Refining Company's mining department, in conjunction with Mr. H. B. Price, engineer for Messrs. Minor C. Keith and Isaac Untermeyer. In consequence of a favorable report a 52% interest was purchased by the principals mentioned from the owners, namely, Mr. R. K. Neill of Spokane, and Messrs. Wood, Trites, and Wilson of Fernie, British Columbia. The management of the enterprise rests with the American Smelting & Refining Company. The present program is to ship the high-grade ore, while erecting a small mill for concentrating the lower-grade ore on tables and by flotation. The upper adit is now 600 feet long; it shows, in addition to mill-ore containing patches of shipping grade, two orebodies rich in silver and gold, each of these ore-shoots being the width of a drift or better, and about 70 feet long. The ore of one averages \$100, as broken; the other, about \$200 per ton. These orebodies follow a fissure that may prove to be one wall of a large lode. The exploratory work as yet is insufficient to indicate to what extent the zone of silicified porphyry, about 100 feet wide and nearly parallel with the upper adit, is actually 'ore'. The high-grade cross-

cut mentioned in our issue of January 17 does not, we are informed, represent an average cross-section of the lode, as it follows a cross-vein. This is true of other cross-cuts from the same adit. Examining engineers, please note! A series of diamond-drill holes is being started from the upper adit and from some of the cross-cuts, in order to ascertain the distribution of ore in a wide zone outside the enriching influence of the cross-veins. Two lower adits, at 250 and 710 feet respectively below the upper one, will be used for deeper exploration; these are now 400 and 550 feet long, respectively. The ore is silicious, being about 75% insoluble; it contains pyrite, galena, blende, and the various minerals of silver, including the native metal, but ruby silver is characteristic.

A Fall in Exchange

"Well, I guess we can get \$30 for our gold in London, now that it has gone to a premium of 50%." Such was a remark we overheard during the past week. On February 4 the price of gold in London was 129 shillings, which represents 55% above normal. Our Californian gold miner was wrong, of course, in supposing that he could get the benefit of the premium in London, because he would receive 129 shillings, not 30 dollars, and 129 shillings on February 3 was worth only \$20.65, which is pretty close to the standard value (\$20.67) of pure gold in New York; in other words, the market value of gold in London had risen as much as sterling exchange had fallen. On the same day silver was quoted at 88½ pence per ounce on Lombard Street while it brought 132½ cents on Wall Street. Formerly we used to multiply the London price, in pence, by two in order to get the equivalent in cents; now we have to do a different and less easy sum in arithmetic. The 88½ pence was the equivalent, at the current rate of exchange, not of 177 cents, but of 122 cents, which simply goes to prove that the price of silver as fixed in New York is largely artificial. On February 7 silver was quoted at \$1.32½ in New York, while it sold for \$1.35½ in San Francisco. On the same date it reached 89 pence in London, which at the exchange rate of \$3.32½ for the pound, was equivalent to only \$1.23½. However, the prices paid for the precious metals was not the most significant phase of the collapse in international exchange. On February 3 the pound suffered a depreciation, as compared with the pre-war rate, of 33%; on that day French, Belgian, and Italian exchange showed a fall ranging from 68 to 77% as against normal ante-bellum days. It was a débâcle. Some thoughtless persons seemed to think it amusing and regarded it chiefly as a compliment to the dollar. The drop in quotations on Wall Street and the semi-panic on the European exchanges served more correctly to reflect the seriousness of the crisis. Its meaning was understood; there it meant a heavy embargo on importation, here it meant a corresponding penalty on exportation. Only a fool would derive any sort of amusement from a condition that threatened to prevent him from trading with his own customers. The suggestion that the British purchase of American cotton might be stopped was taken by sundry yellow journals as a threat

to an American industry, whereas, of course, it was a legitimate and logical consequence of the prohibitive rate of exchange. Cotton is not the only trade that is mortally affected; it is merely an example. We have been doing an export business of three to four billion dollars per annum; during the War and since, our surplus of exports has been stupendous; we have had an opportunity of supplying raw material and manufactures to the war-devastated countries, which needed both, because of their own inability to produce either of them or to obtain them anywhere except from our country. The drain on credit has been excessive; our customers have sent all their available gold to us long ago; they can only pay in goods or in credit; owing to the destruction of plants and the disorganization of industry they cannot send us their products as fast as they import ours; their credit facilities have been undermined by an excessive issue of paper currency; they cannot do business with us unless some restoration of international credit is effected; the fall in exchange, especially in the countries of continental Europe, merely reflects the natural consequences of the wastage and destruction of life, property, and industry since August 1914. Our foreign trade normally is small as compared with our domestic trade, but it is important because it serves as a means of disposing of our surplus; it is a safety-valve regulating the pressure of business; it is a flexible element in our national commerce. Prices at home in large measure are regulated by the intensity of exportation abroad. During the War we exported enormously; we have been living in a fool's paradise, for it is a condition that cannot continue, as the recent break in exchange indicates with a bang. One immediate result will be beneficial; we shall see a radical check on profiteering; prices of staple commodities will fall; H. C. L. will cease to be ominous initials; a surplus of domestic products will be accumulated by reason of a restriction on export; the laws of supply and demand will assert themselves, and the era of rising prices will come to an end. The fall in exchange will do more than the Attorney-General or the Housewives Association to end the orgy of profiteering and extravagance. 'Tis an ill wind that blows nobody good. Meanwhile we may learn another lesson. Chinese walls are out of date. We do not live upon an island in the middle of a lonesome sea. We are part of the comity of nations. No business-man can prosper if his customers cannot pay; if Europe goes bankrupt, we go bankrupt also; that is inevitable. All the world is in the same boat, and it is dangerous to all if anybody rocks it, especially in a rough sea.

The Licensing of Engineers

After 14 months of work, the committee of Engineering Council entrusted with the framing of a model law for the licensing of engineers, architects, and land surveyors, has completed its report. Copies of it have been distributed to the various engineering societies and technical journals. The report describes the methods used in conducting the investigation and then gives the text of the "recommended uniform registration law, to regu-

tate the practice of professional engineering, architecture, and land-surveying". It is intended to give as wide publicity as possible to the text of this proposed law, so that the members of the professions affected may be informed, and, what is equally important, may have an opportunity for discussion. Engineering Council has as yet taken no action on the merits of the question, but expects to do so at its meeting during the current month, when it hopes to receive expressions of opinion, in order that it may be guided as to what action to take. The object of the report, however, is not merely to provide a subject for academic debate, although debate is essential, but to take the first step toward meeting a condition that has arisen. Various States already have enacted laws for licensing or registering engineers, and the general interest in the subject is certain to induce legislation in others at the next session of their legislatures. Moreover, the American Institute of Architects has proposed a model law that is so restrictive of other branches of engineering that unless engineers become sufficiently interested to investigate the matter thoroughly and make their combined opinion felt, they are likely in the near future to find their activities curtailed to an awkward degree. An example of this may be seen in Illinois, where a law for licensing architects was passed several years ago and enforced rigidly. The law was so much in favor of architects, to the exclusion of other engineers, that bitter feeling was engendered, and it was found necessary for the engineers to combine in obtaining the passage of a Structural Engineers' License Law. Illinois, therefore, has two laws to regulate the design and erection of structures, one for architects and one for other engineers. As an example of the endless confusion that would follow a different law for each State, and different laws within the same State, it need only be noted that under the model law proposed by the American Institute of Architects it would be unlawful for any but an architect to design or supervise the erection of a bridge, or any structure consisting simply of foundations and girders.

The time has come for engineers to act together in self-protection and to promote uniformity of regulations; for laws regulating the practice of engineering are being passed, and will continue to be passed, whether engineers co-operate in framing them or not. On other pages of this issue we publish the text of the bill drafted by Engineering Council. A board of registration is to be created for each State, consisting of seven members appointed by the Governor. This board passes upon applications for licenses. Certain facts, in the absence of disqualifying evidence, are accepted as *prima facie* evidence that the applicant is fully qualified to receive a license: for example, ten or more years active practice; or graduation, after a four-year course, from an approved technical school, plus four years of active practice; or, full membership in one of the national societies, such as the American Institute of Mining and Metallurgical Engineers. In case the applicant cannot qualify on any of these grounds, provision is made for the presenting of further evidence, which may include an examination, al-

though it is not expected that many applicants will be subjected to any such examination. In regard to the qualifications required, the report includes the following explanatory note: "The standard of qualification is set high for two reasons: The public welfare will be better promoted by maturer competency, and the prestige attaching to the term 'registered' will be more significant for the professional men themselves. In requiring the younger, less experienced men to serve somewhat longer as assistants or understudies to older men, no hardship is imposed which will not be compensated by the fuller return in recognition when registration is achieved." This seems reasonable. Other parts of the report deal with revocation and renewal of licenses, penalties for practising illegally, and privileges of a registered engineer in States in which he is not registered. Considerable attention is paid to the relation of architecture to other branches of engineering, in an attempt to harmonize the two and obviate the attempts to have legislation enacted that will be unduly restrictive of one branch at the expense of the other. The different branches of modern engineering interlock, and this attitude seems to us a wise one, worthy of reciprocity on the part of the architects, for example. The entire report appears to be carefully considered, and we hope that engineers will give it the attention that it deserves. Here we may record the fact that the mining engineers of Colorado, and also those of British Columbia, made a protest against any system of registration that placed a hindrance upon the examination of mines in a State or Province by engineers from other States or Provinces. This evidence of professional solidarity does credit to our friends in the two great mining regions mentioned, and we have no doubt that engineers in other parts of the United States and Canada will show a similar good-will.

Another interesting feature, arising from the action taken by Engineering Council, is the recognition of the fact that in Engineering Council we have at last an organization well fitted to represent the whole engineering profession in matters of general importance. On January 23 the governing bodies of the national engineering societies met in New York, at the Engineering Societies Building, and on that occasion it was agreed to recommend to each founder society that the amount contributed by each of them for Engineering Council shall be increased from \$3000 per annum to \$5000. It was also resolved that an appeal be made for a contribution of \$2 from every member—except juniors and students—of the five national engineering societies, for the purpose of supporting the welfare work for engineers. A meeting is to be called soon of representatives of national, local, state, and regional engineering organizations for the purpose of creating a comprehensive organization of the engineering profession. This is an epoch-making departure and bears the promise of great things. It sets the mark of approval on the work already done by Engineering Council and indicates the general desire on the part of the various branches of the profession to get together for their own good and for the good of the nation.

DISCUSSION

De-Gassing Cyanide Solutions

The Editor:

Sir: Referring to the letter appearing on page 48 of your issue of January 10, written, it is alleged, for the purpose of preventing "the uninitiated from kidding himself into the belief that the benefits of the Crowe process are obtainable by the arrangements described by" myself, in your issue of September 20, 1919, page 392, the inference being that a given vacuum, say, 15 inches, maintained in a de-gassing tank, such as I described and illustrated, will not remove entrained, occluded, or dissolved oxygen from cyanide solutions if said tank is connected with a submerged vacuum-filter; I have emphatically stated it will remove oxygen together with other gases, and that statement is apodictic.

I have nothing to sell or to advertise in this matter, and, needless to say, disclaim any intention or desire to wrong or mislead anyone, but feeling that better results have been attained and can be uniformly obtained by the old and well-known apparatus described, I have made it known in the best interest of the profession. I fully realize others have been using similar dry-vacuum apparatus for many years not differing in kind but only in degree, particularly regarding the capacity of de-gassing tanks. Those who have large storage in such tanks are to be congratulated; and those who have not, know the remedy. They can either enlarge vacuum-storage capacity, following the best practice in fully utilizing standard milling apparatus, or adopt the patent 'chicken fixins', pay tribute to monopoly, and bear testimony to the saving made in zinc and cyanide.

I join issue directly with Mr. Colbath on the utility and efficiency of the de-gassing apparatus used in Stratton's Independence mill: in fact, there is only one better method I know of, the submerged vacuum-filter used as a clarifier, an apparatus in common use throughout the world these many years.

The submerged vacuum-filter is somewhat irregular in solutions discharged to the de-gassing tank, the maximum flow being coincident with the commencement of the formation of the filter-cakes and that maximum solution-flow usually contains the minimum amount of gases. The opposite condition, minimum flow of solution and maximum amount of gases, occurs when the formed cakes are exposed to the atmosphere during the filtration cycle; so we find a happy balance in favor of the combined filter and de-gassing apparatus, provided the tank is of ample capacity to cover the double object: exposing the necessary solution surface for de-gassing and providing stor-

age for the irregular flow of solution from the filter.

Clarification of some sort is invariably required before precipitation, and there is no better clarifier than the submerged vacuum-filter equipped with a de-gassing tank, as previously described. No matter what form of primary filtration has been used—vacuum, pressure, or gravity—the filtrate from all or each is best clarified in the submerged vacuum-filter and the clear solution pumped to the precipitators direct from its de-gasser. One has not far to look for such an operative arrangement. I have seen designs along similar lines extending back many years, that is to say, a submerged vacuum-filter for treating slimes, the filtrate from which was clarified in a similar, but very much smaller, submerged vacuum-filter and pumped direct from the de-gasser to the precipitators, both de-gassing tanks and filters operated from one dry-vacuum pump.

The instantaneous oxidation of cyanide solutions should not be taken seriously—it will not by the experienced operator; there has been far too much written about it; so far we have no authentic account of spontaneous combustion of cyanide solutions, and writers should be careful not to increase fire-rates on the milling plants of the country; they are already far too high.

Los Angeles, January 30.

PHILIP ARGALL.

The Crowe Process

The Editor:

Sir—Now appears James S. Colbath, all the way from El Paso, with an effusion, printed in your issue of January 10. Allow me to suggest that Mr. Colbath, and the other advocates of the claims of Mr. Crowe, get together and present to him a fitting testimonial for his alleged discovery of a property of an assemblage of well-known materials, whose properties were well known before, and his putting the same to use by means of long-practised and well-known methods and apparatus, which effected the same purpose and end as always before.

Let the testimonial be a leather medal, or one of greater value, even up to a granite monument on top of Pike's Peak, overlooking the site of the great discovery. I am tempted to offer the medal myself.

I started the attack on the Crowe patent—note the distinction between 'patent' and 'process'—for two reasons: One was because I desired to inform and protect the gold-metallurgist from unnecessary payments for the alleged right to use a useful process under the claimed protection of an illegal patent. The other was to set forth an illus-

tration of the deplorable inefficiency of the U. S. Patent Office.

Immediately I was answered by assertions that the alleged discovery by Mr. Crowe was a great advance in cyanide metallurgy of gold; and, by implication only, that the patent is a legitimate one. Let us further examine as to that:

The U. S. patent law states: "A patent may be obtained by any person who invented or discovered any new and useful art, machine, manufacture or composition of matter, or any new and useful improvement thereof, not known or used by others in this country before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof, or more than two years prior to his application."

Thus any patent existing on grounds other than here stated, or through fraud or error, is illegal and void.

Preliminary to an invention there must have been a discovery. A discovery of a principle, as such, is not patentable. But new means and new methods of utilizing such a discovery are patentable as apparatus and processes. Appreciation of the potential value of a discovery may show a talent for progression, and if published to the profession, or artisan, may be of much benefit in the way of foundation for invention. Such publicity is not patentable.

It is acknowledged by Mr. Colbath and the like thinkers that the principle of the alleged Crowe process was long known. Nowhere in the Crowe patent is there a claim of the discovery of the principle. That is not set forth in any of the 31 claims as his invention. All patents are finally construed by the courts according to the virtues of their claims, as defined by the prior state of the arts to which they are related, and the statements made in the application by the patentee.

Mr. Crowe does not set forth in his patent any actually new or original means or method—apparatus or process—for applying to the art of cyanidation the discovery of the principle that the absence of air or other gases is essential to good precipitation of the metals. But he does attempt to appropriate as his invention, in 31 ingeniously worded claims, the methods and apparatus long in use prior to the date of his application for the patent; shown by me in at least four instances cited by me in my previous letters on the subject. And especially in the letter so ably written by Mr. Argall, and which Mr. Colbath attempts to answer.

I am not going to try to answer the rot Mr. Colbath writes about Mr. Argall's experience and apparatus. Mr. Argall is quite able to defend his position, and I believe able to tell even further things still more damaging. He may do so if he happens to think that the "game is worth the candle".

Contrary to Mr. Colbath's statement, cyanide solution has no marked avidity for the absorption of air. While it gives up its absorbed air very rapidly under the influence of a vacuum, to re-aerate it takes much time unless air be forced into it by agitation and pressure. It is absolutely erroneous to assume that de-aerified cyanide

solutions re-absorb air almost instantly under atmospheric pressure.

The conveying of such solutions through pipes out of external air contact is about as old as any of the other of the elements of the combinations set forth in the claims of the patent. Those claimed as new, being identical with the old apparatus and methods so unreservedly appropriated, work now as then and worked then as now. Whether the inevitable results were premeditated is entirely immaterial in relation to patentability.

Credit for setting forth, prominently, the virtues of de-aeration of cyanide solutions may be accorded to Mr. Crowe. The discredit of granting a patent therefore rests with the U. S. Patent Office. Gullibility may be laid at the doors of . . . never mind! Let it go!

Philadelphia, January 20.

N. S. KEITH.

[A reply to the criticisms of the validity of the Crowe patent appeared on pages 14 and 15 of the advertising section of our issue of January 31. Any reader interested in the controversy is advised to read the reply made there by Mr. Charles W. Merrill. We do not care to publish any further letters on the subject, which has now been adequately ventilated.—EDITOR.]

Engineering Employment Bureaus

The Editor:

Sir—The statement of Mr. Bradley Stoughton made in San Francisco and quoted in editorial in your issue of January 3, which applies to the employment work of the founder societies and of A. A. E., calls for correction, for it is inaccurate. The figures that are of interest to engineers are not the men put in touch with positions open, but the number of men actually placed and the cost per placement. In the three months period referred to by Mr. Stoughton, the American Association of Engineers placed 389 men at a cost of approximately five dollars per placement, while the founder societies employment bureau placed 375 men at a cost of about ten dollars per placement. In the interest of accuracy, these facts should be set before your readers.

C. E. DRAYER,

Chicago, January 20.

Secretary.

THE DOMESTIC production of arsenic in 1919, according to estimates compiled by James M. Hill, of the U. S. Geological Survey, was 5900 tons, as compared with 6400 tons 1918. The imports of arsenic for the first nine months of 1919, as reported by the Bureau of Foreign and Domestic Commerce, were 1389 tons. The imports for the year will probably amount to about 1550 tons. Most of the imported arsenic came from Canada and Mexico, though some came from Belgium and Japan. The quantity of arsenic available for consumption in 1919 was 7450 tons, as compared with 7170 tons in 1918. There were no exports either of foreign or domestic arsenic during the first nine months of 1919. Two domestic companies who produced considerable arsenic in 1918 reported to the Geological Survey that they produced none in 1919 on account of low prices.

Some Ideas on Ball-Mill Practice

By CURTIS LINDLEY, Jr.

The suggestions in this article are submitted as an explanation for many peculiar results obtained in the practice of crushing with balls, pebbles, or bars. It may be that the ideas set forth herein are not new, but I have not been able to find a similar expression of opinion in any of the published studies of the subject. My hope is that these suggestions will be of some benefit in solving sundry problems connected with ball-milling.

The first suggestion is based on a probable law for this type of crushing. For instance, we know that we feed material to a ball-mill and obtain finer material therefrom. We do not absolutely know that any particular particle in the feed will be crushed on passing through the mill. In other words, it is possible in a closed circuit for a particular particle to circulate indefinitely. However, this is not probable. In this last statement there is perhaps a clue to the law governing this kind of crushing. The law is that of probability and chance, which is governed by definite formulas. Stated simply, the greater number of chances given for any particle of feed in its passage through a mill, to be acted upon by a force sufficient to crush it, the greater will be the probability of it being crushed.

Let us see how this applies to the operation of these types of crushing-machines. In the comparison of pebble and ball-pebble mills, if we consider both mills to be of the same size, the ball-pebble mill will have the greater capacity, owing to the fact that a greater number of crushing-units can be contained in the critical ball or pebble-volume of the mill, thereby giving a greater number of chances for each particle of feed to be acted upon by a force sufficient to crush it.

Considering the ratio of solid to liquid, an increase in the liquid content causes a more mobile mixture in which the solid particles have greater freedom of action and therefore fewer chances of being caught between the balls when in contact. As a further explanation of this point, two balls approaching a contact in a liquid set up currents of increasing velocity within the liquid. These currents tend to move away from the point of contact and in this way remove particles to be crushed from the crushing-area between the two balls. In a thick pulp the particles are hindered in their movement and certain ones remain in the proper place to receive a blow. The thicker the pulp, the greater the chance for crushing. Aside from the above described action, the solid-to-water ratio can be brought out in another way: Consider two different consistences (by weight) of pulp, one with 30% moisture and one with 50% moisture. There is 70% (by volume) more solid in the former pulp than in the latter. In addition to the effect of hindrance of action of the particles, the thicker pulp, in this case, allows each indi-

vidual crushing force a 70% greater chance to act upon a particle of solid than in the thinner pulp. Disregarding the greater freedom of action of the particles in a thinner pulp, there is an apparent fallacy here, in that the thicker pulp will provide a greater number of solid particles per unit volume to be acted upon by a given number of unit crushing forces than the thinner pulp, and therefore there would be less crushing done. The conclusion drawn from this is that there are two groups of chances to be considered; the first group includes the chances that each unit crushing force is given to act upon solid particles, and the second group is the chances each particle of solid is given to be acted upon by a unit-crushing force. The first group can be more readily understood by a comparison of shooting at one or a flock of ducks, and the second group by a comparison of shooting at one duck with a rifle or a shot-gun.

The mill that offers the maximum number of chances in each group will have the greatest crushing-capacity.

The second suggestion developed from a study of the first suggestion by a few rough computations; it is probably quite different from the general line of theory heretofore offered by authorities on the subject as an explanation of the crushing action in ball, pebble, and bar mills.

From a careful study of the literature of the subject, I find a general consensus of opinion that the greatest amount of crushing done by these mills is accomplished by direct impact of the falling balls upon the material to be crushed, and that only a slight amount is done by attrition.

The suggestion offered is that only a slight amount of crushing is done by direct impact and a less amount by attrition. The principal crushing action, however, is that of transference of crushing force through that portion of the ball mass at rest or nearly so, this action being initiated by the impact of the falling balls. Each ball in the mass at rest, or nearly so, is capable of coming into contact with from three to twelve other balls at the same time. Let us consider any stack of balls in this mass, like the common stack of cannon-balls. Consider it to be five balls high with one ball at the top, four balls in the next lower tier, nine balls in the next lower tier, 16 balls in the next, and 25 balls in the bottom tier. There are, in all, 200 points of contact in this stack. This, of course, is an ideal arrangement considering truly spherical balls of the same size, but it will explain the idea quite thoroughly. Of the 200 contacts, 120 are in direct compression from the weight of the balls above, and 80 are merely lateral contacts having no initial stress. Besides these there would be 25 more contacts between the 25 balls in the bottom tier and the medium supporting them. This would give 145 points of contact under direct compres-

sion. Consider that this stack of balls took position in a pulp of 30% moisture. The volume of solid in this pulp would be about 50% of the total, and the probability would be that one-half the points of contact would hold solid particles in place when the balls came to position. The possibility of a particle of solid matter coming to rest on the top of the top ball is quite remote. Now, suppose a ball of the same weight as those in the stack is dropped from a height of five or six feet and falls directly on the vertical axis of the top ball. There would be no crushing by direct impact, but there would be 73 particles held rigidly, as in so many vises, ready to receive a force transferred through the stacked balls. This does not consider the particles at their points of lateral contact. The number of particles that would receive a force sufficient to crush them would depend upon many factors, but it is easily seen that the greatest amount of crushing is done in this way.

In attacking the problem of this type of crushing through the law of probability and chance, I was unable, by reasonable assumptions, to arrive at a figure that would substantiate the theory of direct impact crushing. There were never enough direct impacts to account for more than about 5% of the work done, hence the development of the idea of transference of forces.

It is hoped that these suggestions will prove useful. From a careful study of them, it seems quite probable that a direct comparison of all types of ball, pebble, and bar mills can be made. That the mathematics of the law of probability and chance can be applied to any great extent is questioned, but an observance of the simple rules, either consciously or unconsciously, is imperative for obtaining the best results.

THE supply of rock phosphate in England, both for the manufacture of super-phosphate and for use in the form of ground phosphate is reported to be far below the requirements. As evidence of this, it is pointed out that imports are over 100,000 tons behind the war standard of 1918. The imports of rock phosphate in September 1919 were only 22,423 tons, compared to 29,000 tons in September 1918, and 36,500 tons in September 1917. Imports for the first nine months of 1919 were 260,000 tons, or over 100,000 tons below that for 1918. It is feared by some English manufacturers of superphosphate that there may be a world shortage of phosphate. They point to the shortage of phosphate fertilizers in South Africa which has prevailed for nearly three years, as further evidence upon this point. Steps are being taken there to utilize more fully the Saldanha Bay phosphate deposits. The difficulty of getting phosphate rock has been acute for some time due to reduced output in North Africa, from which source England has drawn much of her supply, together with the fact that France has been retaining more for her own use. Another cause is the shortage of transportation facilities from our own Florida field, as well as from the fact that there has been a dearth in production in this domestic field—U. S. Bureau of Mines.

'Panel' Stopes in South Africa

The large areas of payable ground encountered on the Government Gold Mining Areas have emphasized the necessity for evolving some method of stoping which will permit the extraction of the ground without unnecessary danger and expense due to collapse of the worked-out areas and consequent closing of main haulage-ways. It is well known that on practically every deep-level mine that is engaged in working out boundary stopes, the drifts connecting these stopes with the shaft, and which pass through worked-out areas, are only kept open at great expense and are the cause of frequent accidents. The obvious method of procedure should be to attack boundary stopes first and work toward the shaft instead of from the shaft, as is the present practice. This has been frequently advocated, and is recommended by textbooks, but unfortunately has never been tried here.

At the Government Gold Mining Areas one of the most extensive blocks is being attacked in the following manner: Raises are driven from the main drift in pairs, with a width of 100 ft. in the face and 300 ft. apart, ventilation being forced up along a brattice. When these raises reach a length of 300 ft. they are connected by headings 100 ft. wide. Doors are then erected in the drift below, which forces the ventilation current through the deviation thus provided. The raises are then continued for another 300 ft. and the operation of connection repeated, when the previous connection is closed by a 'stopping'. This is continued as far as desired. When stoppings are required in the connections the sides are narrowed down to convenient widths to minimize the chances of leakage. The whole block is thus completely honeycombed and provided with countless points for future attack. The ground is also provided with strong panels, or pillars, which will ensure the rigidity of the block and make general movement impossible. When general stoping is commenced from the point farthest from the shaft, the usual 'packs' will be sufficient to protect the working faces. An important consideration is the fact that a sufficient tonnage is ensured by the width of the headings, the number of which can be increased as desired. The present machine efficiency in the headings is excellent. Broken rock will be handled by tracks and winches.

At the New Modderfontein and Modderfontein 'B', panel stoping has been in progress for some months, with the same object in view, but the methods employed are not the same. Raises are put through in the usual manner from level to level, and stopes are then set off simultaneously at measured intervals, with a length of face of 90 ft., leaving panels of 30 ft. between. The stopes are advanced on lines, and connections are put through the panels for ventilation as required. Broken rock is handled with the aid of foot-wall cross-cuts and stope tracks with ore-chutes where required. It is probable that one or the other of the above schemes will be adopted on other large mines of the district. The advantages are so apparent that, where ore-reserves permit, it is the obvious thing to do.

The Cottrell Process in Japan

By RITARO HIROTA and KYOSHI SHIGA

The history of the Cottrell process

in Japan begins with the purchasing of the Cottrell patent-rights in 1916 by T. Wada, representing seven principal mine-owners in Japan, and the International Precipitation Co. of Los Angeles, California, of which Walter A. Schmidt is president. Prior to this, negotiations were opened between Mr. Wada and the International Precipitation Co. through H. W. Paul, the company's agent for Japan.

An experimental precipitator consisting of 16 pipes of 12 in. diameter and 16 ft. long, with a capacity of 3000 cu. ft. of smoke per minute at a velocity of 4 ft. per second, was erected in the compound of the Ashio smelter by the Metallurgical Research Institute, Tokyo, of which Mr. Wada is the president.

This experimental treater with the electrical equipment was erected according to the design and suggestions of the International Precipitation Co. in October 1916. The tests were conducted by the engineers of the Metallurgical Research Institute, assisted by F. B. Church and K. I. Marshall, engineers of the International company, who were in Japan at that time in connection with the treater installation of the Asano cement factory at Tokyo. The plant proved satisfactory, treating the mixed gases coming from the roasting-pots, blast-furnaces, and converters of the copper-smelter and precipitating the dust containing oxides of arsenic, zinc, and lead, as well as a small amount of copper.

Among mines and smelters, the Ashio copper smelter of the Furukawa Mining Co. was the first to apply the results of these tests.

The Asano Portland Cement Co., of Tokyo, was having considerable trouble with residents in the vicinity of the plant, because of the dust nuisance. If this nuisance had not been abated by December 25, 1917, the Asano company would have been obliged to move this plant to some other locality. Confronted with this difficulty, and learning of the successful results obtained at the plant of the Riverside Portland Cement Co., the Asano company decided to adopt the Cottrell process at its factory. As the time-limit was definite, they proceeded immediately to build the plant. Before the patent-rights were legally

transferred to the Asano Portland Cement Co. by the International Precipitation Co., the latter had already installed the Cottrell process in its T. K. plant at Riverside, California. K. I. Marshall was sent to Japan to assist in the construction after the design was completed by the I. P. Co.

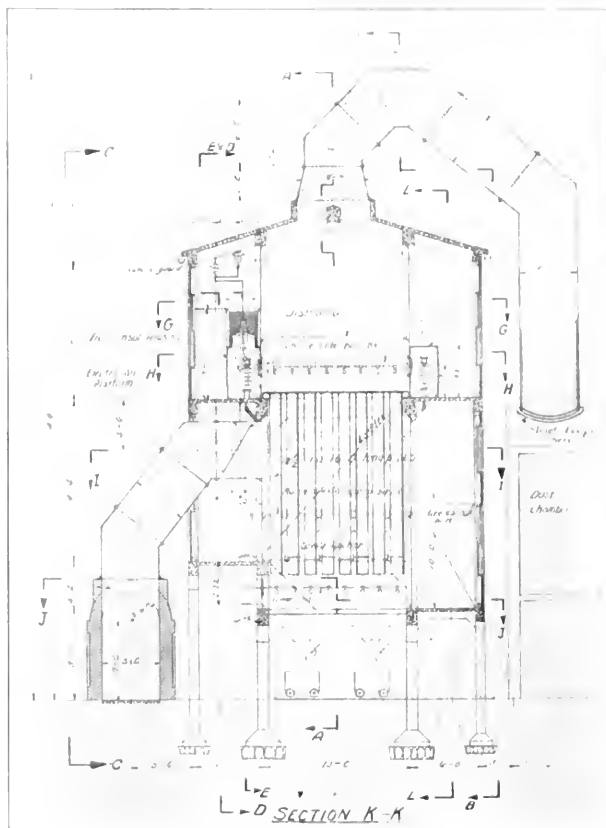

FIG. 1. SECTIONAL ELEVATION OF IKUNO TREATER

Their effective efforts benefited not only the Asano cement factory, but also the community in general, as the Cottrell plant, starting a few days before the specified time, caught more than 95% of the dust causing the nuisance.

The introduction of the Cottrell process was made a part of the business undertaken by the Metallurgical Research Institute, where general metallurgical re-

searches are made by competent engineers and scientists. Special attention is paid to the SO_2 gas and dust problems, as well as to different subjects in ore-dressing.

To perfect designs of Cottrell installations for prospective customers and to study the actual operation of Cottrell installations in the United States, the Metallurgical Research Institute sent Mr. Shiga to the International company at Los Angeles, where he studied the design and operation of precipitators. In May 1917, after completing his study, Mr. Shiga was joined by Dr. Hirota, manager of the electrical precipitation department of the Metallurgical Research Institute, and together they visited the principal smelters and factories in the United States in which the process has been installed, including the plants at Miami, Garfield, Tooele, Anaconda, Riverside, Hagerstown, the Duquesne Reduction works, the Pennsylvania Smelting Co., the Portland Gas works, and the Merrimac Chemical Company.

In the meantime orders were placed with the Westinghouse and General Electric companies, and the Kelman Electric Co. of Los Angeles, for electrical equipment, such as extra-high-tension transformers, motor-generators, and rectifiers. Orders were also placed with the Western Pipe & Steel Co. of San Francisco, and the Robertson Bros. Co. of Chicago, for pipe-electrodes, to be used in treater installations at the smelters belonging to the Mitsui and Mitsubishi companies.

Since the return of Dr. Hirota and Mr. Shiga to Japan in the fall of 1917, several plants have been equipped with Cottrell installations, and with the aid of the engineers of the Metallurgical Research Institute, these plants are now working satisfactorily, eliminating the smoke and dust nuisance, and collecting many tons of valuable dust, which was hitherto going to waste.

The Research Institute did not lose the opportunity of making the Cottrell process widely known, and it has exhibited a model installation at the expositions in Tokyo and Osaka. Lectures have been delivered by Dr. Hirota at the meetings of the Mining Engineers, Mechanical Engineers, and Railway Association, and by Mr. Shiga before the Chemical Industrial Association, and the Smoke Abatement Association of Osaka City.

Thus the Cottrell process, although only a few years old in this country, has made comparatively rapid progress. Eight treaters, having a total of 1984 pipes, have been built and are now operating. However, on account of war conditions, there has been considerable difficulty in procuring electrical equipment, pipes, and other material. This has hindered development of the process. Engineers and metallurgists in Japan are eagerly investigating it, and several companies now intend to install precipitators for collecting sulphuric acid fumes coming from acid-boiling kettles and acid-concentrating furnaces; for cleaning iron blast-furnace gases used for firing boilers and hot stoves; and for collecting sulphuric acid liberated from alumina calcination furnaces. The Research Institute has already submitted designs and specifications to the Imperial Mint, Shikama alum factory, Kanto Sanso alkali works, Hokkaido Iron & Steel

works, and the Fujita Mining Co.'s plant. The Imperial Mint has quite recently decided to install a plant for collecting sulphuric-acid fume from acid-boiling kettles. It is clear that this process, developed in the United States during the past decade by Dr. F. G. Cottrell, is already being adopted quite extensively in this part of the world.

The following are brief descriptions of the electrical precipitators installed in Japan up to the present time:

ASHIO SMELTER, FURUKAWA MINING Co. There were two treaters installed in 1918; one, the 'main treater', was intended to treat the mixed gases from four McDougall roasters, two blast-furnaces, and four converters of the copper-smelter; and the other, called the 'reverberatory treater', was intended to treat the gases from a reverberatory furnace that had passed through waste-heat boilers. Each treater is furnished with an independent power-plant. Six electric units are being used for the main treater, one unit being spare, and two are used for the reverberatory treater. Each electric unit consists of the following General Electric equipment: one 10-kva., 50-cycle, single-phase, 200 to 100,000-volt transformer; one 10-kva., 200-volt, 50-cycle, single-phase alternator driven by a 15-hp., 50-cycle, 500-volt, three-phase induction motor; and a disc rectifier, manufactured by the Kelman Electric Co., directly coupled to the motor-generator shaft. Besides these machines, exciter sets for the excitation of the field of the two alternators are furnished, two for the main treater and two for the reverberatory treater. The charging voltage is adjusted by regulating the intensity of the field current of the alternators. By this means, it is possible to produce practically any desired voltage at the secondary terminals of the transformer.

The main treater consists of ten sections, each containing 64 riveted pipes, arranged in a square, making a total of 640 pipes; while the reverberatory treater consists of three similar sections, or a total of 192 pipes. These pipes, 12 in. inside diameter and 16 ft. long, of No. 16 sheet-steel, were manufactured by the Western Pipe & Steel Co. The gases are drawn through the main treater by two induced-draft fans, and are discharged directly from the fan-casings, while those of the reverberatory furnace are drawn through the reverberatory treater by the natural draft in the stack. As the reverberatory furnace is not operating continuously at present, the gases from eleven pot-roasters, four blast-furnaces, and four copper converters are mixed and treated by the main treater. Thus the volume of gas now handled by the main treater is probably somewhat in excess of 150,000 cu. ft. per minute, for which it was designed. The amount of dust collected varies from six to ten tons per 24 hours. The efficiency of precipitation seems to depend upon the nature of the furnace-charge and the moisture and temperature of the gases treated. When the conditions are favorable, it runs as high as 98%; sometimes it drops to about 70%. When the conditions are such that the charging voltage can be raised above 80,000 volts with a comparatively small increase in the

current, the results are good. Actual experience at the smelter has shown that when the smoke has a white appearance, precipitation is satisfactory. On the contrary, when the smoke coming from the treater-outlet has a yellowish appearance, the efficiency of precipitation is not so high and the current increases greatly if the operator tries to raise the charging voltage. The smelter engineers are now investigating this phenomenon, and hope soon to get entirely satisfactory precipitation, regardless of the different smoke conditions. The average power consumed by the precipitator is about 30 kilowatts.

C.	99	As	0.8
Fe	10	S	0.84
SO ₂	8	CO	0.4
CO	1.1		

Thus the electrical precipitator collects not only the poisonous dust, such as arsenious oxide, but also the fine particles that hitherto were escaping into the atmosphere, and that perhaps were acting as nuclei for the concentration of noxious gases, such as SO₂, preventing their free diffusion. Such poisonous dust and concentrated noxious gases cause damage to vegetal growth. The

FIG. 2. ASHIO PLANT, TREATER NOT IN OPERATION

FIG. 3. ASHIO PLANT, TREATER IN OPERATION

Several years ago a large dust-chamber was built, using the Roosing wire system. The gases passed from this chamber to four large stacks, in which they were diluted by the forced admission of fresh air, before being discharged into the atmosphere. The main treater was installed at the side of this dust-chamber, so the gases pass through the chamber, before going through the treater. The numerous suspended wires in the chamber were removed, so that only the heavier dust, which is of more value because of its higher percentage of metals, would be caught; and all the lighter dust, which cannot be efficiently collected by gravity settling, would be arrested in the Cottrell treater.

An analysis of one sample of the precipitate from the Ashio main treater follows:

smoke nuisance has, therefore, been greatly reduced by the Cottrell installation.

As the analysis shows, the precipitated dust contains rather large quantities of the oxides of arsenic. These oxides are extracted by subliming the dust in a small reverberatory furnace. The resulting cinders, rich in copper, are sent back to the pot-roasters after being briquetted.

KAMIOKA SMELTER, MITSUI MINING CO. This treater consists of three sections, each containing 64 riveted pipes arranged in a square, or a total of 192. It was installed and started in May 1918. The pipes, 12½ in. inside diameter by 16 ft. long, made of No. 14 gauge sheet-steel, were manufactured by the Western Pipe & Steel Co. The gases passing through the treater come

from the following furnaces, three lead blast-furnaces, two liquation furnaces, five softening furnaces, and all the lead-refining furnaces and kettles. At first it was intended to install a treater having four sections of the same size as those specified above, and three electric units. In fact, three 15-kva., 200 to 100,000-volt transformers, and three motor-generator sets were ordered from the Westinghouse company. On account of the delay in shipment of this electric equipment, due to labor troubles and difficulties of transportation caused by the War, the size of the treater was reduced and temporary electric machines were substituted until those from the Westinghouse company arrived. The Kamioka smelter is situated in the heart of the sericulture district, and the residents in the vicinity made strenuous objections and demanded heavy indemnities, claiming that the smoke damaged the mulberry leaves and killed the silkworms. Therefore, every effort was made to complete and start the Cottrell plant at an early date. The temporary machines, supplied by the Metallurgical Research Institute, consisted of high-tension transformers, the voltage of which was regulated by an induction regulator, and K-1 type rectifiers driven by synchronous motors. The precipitator worked continuously without trouble, and from 1 to 1.5 tons of dust per 24 hours was collected, even though the temporary electric equipment was being used. The Westinghouse equipment has since arrived and is now installed.

Analysis of the precipitate is as follows:

	%		%
As	19.65	SO ₂	0.63
Pb	57.26	Zn	3.68
Cu	Trace	Ag	0.0063
Bi	0.16	Au	Trace
Fe	0.16	Insoluble residue	0.31
Total S	5.91	Moisture	0.90
Free S	1.13		

The voltage for charging the treater is about 70,000 volts and the consumption of power is approximately 6 kw. Not only has the Cottrell process settled the smoke nuisance, but it has also been the means of saving dust that is valuable to the smelter because of its high metallic content. Hence, this plant, although small in size, presents the most striking example of the benefits that have been derived from the process, both by the public and the smelters in Japan.

NAOSHIMA SMELTER, MITSUBISHI MINING CO. The erection of this smelter was permitted by the Government on the condition that the effluent gases would be cleaned by the Cottrell process. The operation of the treaters was therefore begun when the smelter started, in March 1919. The treater consists of five units, each containing 64 lock-seam pipes arranged in a square, or a total of 320. These pipes, manufactured by the Robertson Bros. Co., are 12½ in. inside diameter by 16 ft. long and are of No. 14 gauge sheet-steel. The treater was designed for a capacity of 80,000 cu. ft. per minute, assuming a velocity through the pipes of five feet per second. The lead-bearing fume from the smelting-furnaces and the fume from the McDougall roasters and the converters are mixed, and treated together in the precipitator. Natural draft is furnished by a stack 150 ft. high and 10 ft. inside

diameter. The electrical equipment consists of three Westinghouse units, similar to those described above for the Kamioka smelter. As the delivery of these machines was delayed, the plant was started using temporary machines, as at Kamioka.

The smelter having only recently been started, the furnaces are not yet running at their full capacity and the volume of gas handled runs from 40,000 to 45,000 cu. ft. per minute. The efficiency of precipitation is so high that practically no visible smoke issues from the stack and the people scarcely realize that such a large smelter is in operation.

The dust collected per 24 hours amounts to about 1.5 tons, and its analysis is as follows:

	%		%
Cu	2.30	Au	Trace
Pb	22.54	Ag	100 gm./ton
Fe	11.20	Sb	3.14
S	12.60	Zn	3.29
As	13.43	Loss on heating	25.68

After much study and discussion, 64 pipes, arranged in a square, as designed for the Naoshima treater, were chosen as the standard treater unit by the Research Institute. For small plants, 32 pipes, arranged in a rectangle 8 by 4, or half the size of the standard unit, are used. This plan was adopted to facilitate the design and erection of plants, the object being to benefit by the standardization of parts. A sectional view of the Ikuno treater, which is very similar to the Naoshima treater, is given in Fig. 5.

IKUNO SMELTER, MITSUBISHI MINING CO. The treater at this smelter handles the gases from two blast-furnaces smelting copper ores. It consists of two sections, each having 64 lock-seam pipes, arranged in a square. These pipes are 12½ in. inside diameter and 16 ft. long, and are of No. 14 gauge sheet-steel. The gases, after passing through an old dust-chamber, are drawn through the treater by an exhaust-fan and are discharged from the old stack into the atmosphere. Two sets of electric equipment, one unit to be spare, and each consisting of a 15-kva., 200 to 100,000-volt, 60-cycle, single-phase transformer, and a motor-generator set, were ordered from the Westinghouse company. In January 1919 this treater was started, using temporary equipment. At the first trial, the treater showed good efficiency. This efficiency lasted only a couple of days, and then the operation became so unsatisfactory that the diminution of smoke could scarcely be recognized even when the treater was charged with high potential. After experimenting in various ways, it was decided to humidify the gases, a practice which was found necessary for satisfactory precipitation in several American plants. A dozen orchard spray-nozzles of ¼-in. diameter, arranged in the dust-chamber, using water at a pressure of 120 lb. per square inch, injected a fine spray into the gases before they entered the treater. Precipitation was conspicuously improved and the efficiency raised to about 95%. Now the operator can raise the charging voltage to 80,000 volts while the current is only approximately 30 amperes. When, in order to examine the effect upon precipitation, the water sprays are turned off, the charging potential

FIG. 5. ASHIO TREATER. TOP OF ELECTRODES

drops and the current increases so that the efficiency becomes as low as 50%. This experiment shows that smelter smoke, difficult to precipitate on account of its non-conductive properties, is often easily treated after being humidified.

The amount of dust precipitated per 24 hours is about 0.6 of a ton, and its analysis is as follows:

Ag	0.0007	Zn	0.80
Pb	7.80	CaO	0.20
Cu	0.50	MgO	Trace
Bi	2.48	SiO ₂	1.95
As	32.30	S	12.17
Sb	Trace	SO ₂	0.78
Sn	10.80	H ₂ O	5.10
Fe	1.01	Cl ₂ etc.	12.32
Al ₂ O ₃	0.20		

NIKKO ELECTROLYTIC COPPER REFINERY, FUKUOKA MINING Co. Here the gases from two cupellation and two reduction furnaces are treated to recover silver-bearing lead fumes. The treater consists of one section of 32 pipes, arranged in a rectangle 8 by 4. These pipes, manufactured by the Western Pipe & Steel Co., are 12½ in. inside diameter by 16 ft. long, and are of No. 14 gauge steel-plate. The treater was designed to handle a gas volume of 8200 cu. ft. per minute. The actual volume is about 6500 cu. ft. at a temperature of from 100° to 200° C., and is drawn through the treater by an exhaust-fan. The electric equipment consists of a 10-kva., 50-cycle, 200 to 100,000-volt transformer, manufactured

FIG. 6. ASHIO TREATER. BOTTOM OF ELECTRODES

by the American Transformer Co., and a rectifier of the rotary-arm type, 30 in. diameter, supplied by the Research Corporation in New York. The rectifier is driven by a 14-hp., 220-volt, three-phase Westinghouse synchronous motor. The transformer has taps on the low-tension windings which will give voltages of 50,000, 62,500, 75,000, 87,500, and 100,000 on the secondary. These taps, together with a small capacity rheostat in the transformer primary circuit, afford sufficient range in voltage.

The treater was started in May 1919. The analysis of the precipitated dust is as follows:

Ag	51.90
As	11.23
Cu	
No	Pb
0.0886	Se
0.23	

FIG. 7. NIKKO COPPER REFINERY

The amount of the precipitate is about 100 lb. per 24 hours. The consumption of power is comparatively high, ranging between 2.5 and 5 kilowatts.

ASANO PORTLAND CEMENT Co. Two precipitators were installed at the Tokyo factory of the Asano Portland Cement Co. in 1917; one for the rotary kilns and the other for the lime-kilns. They consist respectively of three and two standard units. Both treaters are energized from a central power-house in which four electric units are situated. Each unit consists of a 200 to 75,000-volt, single-phase, high-tension transformer and a motor-generator-rectifier set. All this machinery, with the exception of the rectifiers, was manufactured by the Allis-Chalmers company. The rectifiers were built by the Kelman Electric Co. The three-phase induction-motor

of the motor-generator-rectifier set furnishes power to the single-phase generator and to the rectifier. Power for the primary circuit of the transformer is supplied by the single-phase generator. The high-tension transformer current is changed to a uni-directional current by the rectifier, and as such, is impressed upon the treater-electrodes. The treater-discharge electrodes, made of No. 14 iron wire, are charged with a uni-directional current of negative polarity.

The volume of gases handled by the rotary-kiln treater

FIG. 8. TRANSFORMER AND RECTIFIER

is about 70,000 cu. ft. per minute at a temperature of from 250° to 300°C. Eight to ten tons of semi-calcined cement dust is collected per 24 hr., the efficiency being about 95%. The lime-kiln treater handles 40,000 cu. ft. per minute at 80°C., and the efficiency is from 80% to 90%. The high-tension voltage used is from 50,000 to 60,000 volts and the total consumption of power is approximately 12 kilowatts.

The dust collected in the treater is very fine and dark gray in color. An analysis of one sample is as follows:

Loss on ignition (including 2.75% of carbon)	%	K ₂ O	%
Moisture	7.13	Na ₂ O	6.69
SiO ₂	0.37	SO ₃	1.83
Fe ₂ O ₃	24.61	Cl	4.14
Al ₂ O ₃	2.30	Insoluble residue	2.95
CaO	9.10		4.04
MgO	34.66		100.00
	1.55		

Mining and Milling Tin-Tungsten Ore in Tasmania

By WM. E. HITCHCOCK and J. R. POUND

*The S. and M. mine, which is the property of the S. and M. Syndicate, London, is situated at Moina, in north-west Tasmania, 18 miles from Staverden railway station and 36 miles from Devonport. In common with the inland districts of north-west Tasmania, the country facing from the high interior table-lands is much broken by deep river gorges, thus confining the main roads to the spurs between these gorges. Much of this district is covered with basalt, and, except when cleared, carries a dense growth of timber and scrub. In many places, however, various exposures of the mineral-bearing rocks are to be seen. Those in the vicinity of the S. and M. mine are granite, porphyry, quartzite, conglomerate, a lime-silicate rock (locally called garnet), and limestone.

GEOLOGY. The tin-tungsten lodes are a complex of veins traversing beds of sandstone or quartzite and lime-silicate rock. These rocks form a contact metamorphic aureole surrounding a mass of granite and granite-porphyry which is exposed further east and south for a width of between two and three miles, and for about a mile from north to south. This exposure of granite represents one of the many uprisings of acidic magma which occurred in different parts of Tasmania during the Devonian period. The occurrence of the lime-silicate rock at the S. and M. mine points to the alteration of original limestone within the zone of contact-metamorphism. The rock consists of magnetite, fluorite, garnet, and vesuvianite, with epidote and veins of pink feldspar. The contact-metamorphic minerals are, on the other hand, absent from the mineral lodes in this rock. The lode gangue consists mainly of quartz, topaz, fluorite, and mica. Its structure is pegmatitic, and the tin, tungsten, bismuth, and molybdenum ores are pneumatolytic in nature and origin. The economic minerals at Moina may be considered as having had their source in the granite magma. The pegmatitic veins both in the granite and the surrounding aureole harbor ores of tin, tungsten, bismuth, and molybdenum, indicating deposition from metal-bearing igneous emanations. At a greater distance from the granite boundaries the metallic vapors were replaced by magmatic waters in an outer hydathogenic zone, giving rise to the deposition of galena and zinc-blende—for example, at Wilmot River, Lea River, Five-Mile Rise, etc.

THE MINE. At the S. and M. mine five lodes are worked. They are nearly vertical. A striking feature is the persistence of the lodes in length and the fairly uniform widths. Bulges or pinches do not occur, but the lodes frequently split into veins, the aggregate widths of which are usually that of the lodes where solid.

Nearing the lateral limits the lodes become reduced in size, and usually split up into small veins. The gangue consists of quartz accompanied by fluorite, mica, and topaz, and the minerals are cassiterite, wolframite, scheelite, bismuthinite, bismutite, and pyrite. Chalcopyrite and molybdenite also occur sparingly, and galena has been noted. The rocks strike north and south, and dip to the west. The ore-bearing lodes traverse these at right-angles to the strike, and pass from the quartzite to the overlying garnet without change. A faulting of some 3 ft. occurs at the contact, which dips about 50° to the west. The ore does not occur in shoots, but is irregularly distributed, and it is consequently necessary to take out the whole length of the lodes to avoid missing the richer patches, of which there is usually no indication until they are met. The lodes have no walls, and, as there is no gouge, they cannot be broken down separately. It is therefore necessary to break the country-rock on each side to the working width of drift or slope. A disadvantage exists in that a considerable amount of waste-rock is mixed with the ore, and this especially when the lodes split into veins which separate over a width of several feet. Basalt covers the western portions of the lease to the extent of nearly two-thirds of the area (320 acres), but fortunately the quartzite and garnet rocks show up along the eastern boundaries, thus enabling the lode outcrops to be picked up and followed under the basalt.

At present the greatest depth of the workings from the surface is 300 ft., and the lodes at this depth, as compared with those at the surface, do not show any serious lowering in tenor in tin and tungsten. The bismuth tenor, however, does show a reduction, as the richer patches were found near the surface. Some of these patches yielded as much as two tons of carbonate of bismuth.

The lodes are worked by adits and from a main shaft. No. 3 adit, which is the lowest, has been driven southeasterly for 1230 ft. This adit is the main outlet to the mill. The main shaft has been sunk to the present depth of 171 ft. below No. 3 adit, and was also raised through to the surface, a distance of 96 ft. The main shaft is 11 ft. 6 in. by 4 ft. inside the timbers, and is divided into three compartments, of which two are used for hoisting and a third for ladders and pump-way. Hoisting is done mainly by an air-winch situated at No. 3 adit, to which level the ore is raised and trammed to the mill on trucks of 11 cu. ft. capacity. At the surface a second winch and head-frame have been installed, and as an alternative this plant is used, under steam, during shortage of water for power. In this event the ore is hoisted to the surface and sent to a dump with a capacity of 1000 tons,

*Abstracted from the proceedings of the Australasian Institute of Mining Engineers.

whence it can be drawn off, through a pass, to No. 3 adit level, as required. This is useful especially when milling has to be suspended owing to dry periods or repairs, and enables development work, at least, to be carried on independent of milling.

The methods adopted in development work and ore-breaking are as follows: Levels are driven along the lodes for convenient lengths, say 200 to 300 ft. The drilling is done with $2\frac{1}{2}$ -in. Holman reciprocating machines rigged on upright bars with cross-arms; 11-in. octagon steel, with chisel bits, is used. Where practicable two headings are driven alternately by the machine-men, who, after drilling out one end, shift to another, and while they are engaged in drilling the second the first is blasted and cleaned up. When the level has been driven for the required distance, a start is made from the end to stope the back of the level. For this purpose telescope hammer-drills are used, operating from the floor of the level; the temporary air and water pipes are taken off as stoping progresses. 'Uppers' 4 ft. in height are drilled, spaced 2 ft. 6 in. apart, and staggered on each side of the lode. Blasting closely follows the drilling, and a second cut 4 ft. in height is drilled and fired. The broken ore is left on the floor of the level until the whole length is broken down to a height of about 15 ft. above the rails. The back of the stope is left drilled out for its whole length, and, these operations being completed, a start is made to tram the ore. As the ore is removed it is followed closely by the timbering, and the waste-rock is hand-picked and thrown on top of the timber. Chutes and man-ways are formed, and a minimum depth of 2 ft. of filling is placed on the lagging. Shovel boards are laid on top of this filling, which has first been covered with a layer of sacking to avoid loss of fine ore in the interstices. It is usual, to avoid breakage of caps or stulls, to put in a temporary centre leg. This precaution has been found necessary, as occasionally the force of the blast will be downward, and in such instances the filling does not always save breakage. The timber used is 7 by 7-in. split hardwood lagged with 6 by 11-in. split laths. The caps or stulls are hitched into the walls, and supported by one or two legs, according to the span or circumstance. The objective, however, is to have the stulls or caps independent, as far as possible, of the legs, although these are put in. This is useful in taking out the last stope of the level below, and facilitates the picking up of timbers during that work. In the stoping operations one or more machines are set to work to drill the back of the stope for its whole length, which may be 300 ft. or more. This being completed, the machines are moved to another stope, and blasting is done in several sections along the first stope. After two 4-ft. cuts are broken down the waste rock is hand-picked and the ore is shoveled into passes.

The machine-men, both on Holman and telescope-machines, do not usually do their own blasting, but as far as practicable are engaged for their whole time in drilling. The amount of waste rock does not suffice for fill-

ing, and this is supplemented from other sources; but if such is not available, stalling is put in and another start is made above. The rock is good for standing, and there is no side weight or pressure. It is probable, however, that, as the workings at the shaft levels become more extensive, rill stoping will be resorted to, and all the broken material will be sent to the surface, where sorting can be done on a picking-table or belt and the waste-rock sent down through passes to the stopes for filling. The underground work is all done on wages, and no contracting is at present in vogue.

THE MILL. In considering the flow-sheet, the nature of the ore requires some little explanation. The lodes consist mainly of quartz of a fairly friable nature, enclosed in rocks which are hard. The minerals are easily freed from the gangue, and probably 60 to 70% is already freed before reaching the mill. The wolframite and bismuthinite occur in lumps and patches, and the cassiterite in coarse grains up to $\frac{1}{2}$ in. or more in diameter. After the ore has passed through the rock-breaker little remains to be freed, and after reduction by the rolls to a maximum of $\frac{1}{2}$ in. diameter, practically the whole of the balance is liberated. Thus, reduction does not enter largely into the process. The country-rock, especially the quartzite, contains fine grains of pyrite disseminated through it, and the garnet rock contains much magnetite. The objective, therefore, is to liberate the valuable minerals and as little as possible of the impurities.

The concentrates from all machines in the mill are produced in two grades—namely, 'firsts' and 'seconds'. The objective with regard to the 'firsts' is to retain all the valuable minerals, but to reject the pyrite and silica, and with the 'seconds' to retain the pyrite and reject the silica as far as practicable. By making a 'seconds' product it is possible to aim at a clean 'firsts' product which is practically free from pyrite and magnetite.

The percentages of contents of 'firsts' and of 'seconds' are approximately as follows:

● %		● %	
'Firsts'		'Seconds'	
Fe	35.0	Su	12.0
SiO ₂	35.0	WO ₃	10.0
Bi	2.5	Bi	3.5
Total	72.5	Total	25.5

With the large amount of magnetite which occurs in the inseparable country-rock in the mill ore, any attempt to obtain clean 'firsts' only must result in loss. A 'seconds' product retaining the pyrite and a considerable amount of magnetite is therefore made—not that the pyrite and magnetite are of value, but because they cannot be rejected in wet concentration without loss of metal.

The first step in milling is reduction by a rock-breaker. The ore is hand-fed to this machine, and the feeding is regulated by the capacity of the mill, or, vice versa, the rate of feeding regulates the amount milled. The capacity of the mill is 4 tons (of 22 cu. ft.) per hour, and the feeding of this is, with good facilities, quite within the power of a strong boy. In addition, the feeder picks out from the ore any pieces of steel.

It is proposed to install a bin between the breaker and the rest of the mill, and use a mechanical feeder. Some little difficulty, however, exists in that such a course will necessitate the breaker being run 'dry', and, as a proportion of the ore is wet, probably a tendency to clog in the breaker will occur. The main advantages will be in regular feeding and in having the breaker as a separate unit, the stoppage of which will not involve the stoppage of the mill. The breaker is of the Blake type, the jaw opening being 9 by 16 in. Manganese steel liners of hollow pattern are used. From the breaker the ore, assisted by water jets, passes to a conical trommel 4 ft. 6 in. long and 24 in. to 33 in. diam. The screens are punched with $\frac{1}{2}$ -in. round holes, and make 20 r.p.m. The under-size passes to a series of trommels and the over-size to the rolls. The rolls are 26 in. diam. by 10 in. face, and are gear-driven at 35 r.p.m. From the rolls the ore is raised by a bucket-elevator to a cylindrical trommel 22½ in. diam. by 6 ft. long, the screen of which is punched with $\frac{1}{2}$ -in. holes. The over-size from this trommel returns to the rolls and the under-size to the series of trommels, the largest screens having $\frac{3}{4}$ -in. holes and the smallest $\frac{1}{16}$ -in. The sized products from these trommels go to jigs, which yield products from sieves through gate discharges and from hutches. From the gates from the first compartments the $\frac{3}{4}$ -in. and $\frac{1}{2}$ -in. over-size consists of 'firsts' concentrates; these are hand-picked for bismuth ore and for scheelite, and are then bagged as 'firsts'. From the gates from the second compartments the concentrates, after hand-picking for bismuth ore and scheelite, are passed through a pair of 18 by 10-in. rolls and are then returned to the mill circuit. From the hutches of the first compartment is obtained a product which, after hand-sieving, is good enough for 'firsts'; and from the hutches of the second compartment is obtained a product that either is made good enough for 'seconds' by the same process or is returned to the mill circuit. The sizes from the $\frac{1}{2}$ -in. and $\frac{1}{4}$ -in. trommels are fed to suitable jigs, and the under-size from the $\frac{1}{16}$ -in. passes to a pair of hydraulic classifiers. Spigot discharges from these classifiers provide feed for a fine jig. The overflow from the hydraulic classifiers passes to two Rittinger classifiers, from which the spigots feed Wilfley tables, and the overflow goes to a two-compartment settler. Although a fairly good concentrate is obtained from the tables, it is not considered advisable, on account of the varying metal contents of the feed, to attempt to make a clean product. The tailing from the Wilfley tables was for a time passed over a fine jig, but the results did not justify this. The settler provides feed for two Frue vanners.

All the concentrates produced are drained and dried. The drier is constructed of two $\frac{1}{2}$ -in. plates, 6 ft. long by 3 ft. wide, with angle-iron sides, laid in tandem on brick walls. A small furnace at one end, so arranged that the flame does not come in contact with the plates, provides the heating. After drying, the concentrates are bagged in 1-cwt. bags and dispatched to a magnetic separation works at Launceston and owned by the Syndicate.

POWER. Water power for compressor, pumps, concentrating mill, and saw bench is obtained from a race $5\frac{1}{4}$ miles long. The grade of the race is 16 ft. per mile, and the width at bottom is 20 in. The race passes through forest country and frequently along precipitous sidings. The fall of 16 ft. per mile is necessary to prevent accumulations of leaves and debris, and the basaltic soil in which the race is excavated does not erode, but rather tends to wear rounded with this fall. The main pipeline is 1700 ft. long, and ranges in diameter from 20 in. at the intake down to 11 in. at the mill. Branches convey the water to the pumping plant and to the compressor drive. In all cases Pelton wheels are used under heads of 350 ft. at the compressor and pumps and 375 ft. at the mill. For the rock-breaker, the speed of which is variable, a 36-in. diam. Pelton wheel is provided. A 60-in. diam. Pelton wheel drives the rolls, trommels, elevator, and coarse jigs, the speed of which to a certain extent is variable according to the work on the rolls. A $\frac{3}{4}$ -in. nozzle is used for this wheel, and a $\frac{1}{2}$ -in. nozzle for the fine jigs, Wilfleys, and vanners.

For air-compression a two-stage enclosed type belt-driven machine, of 400 cu. ft. free-air capacity, is driven by a 44-in. Pelton wheel. The nozzle diameter is 1½-in., and a 12-in. link leather belt is used as a drive from Pelton wheel to compressor.

The water supply can be relied upon for 9 to 10 months of the year. Storage is not obtainable within 6 or 7 miles of the mine, and beyond this only to a limited extent. To obtain a supply of water for the whole year would involve a heavy capital expenditure, and there would still be doubts as to its permanency. As a standby an auxiliary steam-plant has been installed. This consists of two Robey locomotive-type boilers, each of 500 sq. ft. heating surface, with fire-boxes adapted for 5-ft. wood. The steam pressure is 135 lb. per square inch. A vertical high-speed 2-stage air-compressor, with compound steam ends, has a capacity of 400 cu. ft. of free air. When water-power is available and compressed air is cheap, hoisting is done by an air-winch, situated at No. 3 adit. As an alternative, a steam-winch at the surface is used for hoisting ore and water. With good wood (myrtle and sassafras cut green and allowed to dry), one boiler is able to steam for compressor and hoist on a consumption of about 220 cu. ft. of wood per 8-hour shift. This includes the wood necessary for raising steam.

Since milling was started by the present owners, in 1907, the quantity milled to December 31, 1918, has been 72,884 tons of 22 cu. ft. The production of concentrates from this has been as follows:

	Tons
'Firsts', containing Sn, WO ₃ , and Bi	822.60
'Seconds', containing Sn, WO ₃ , Bi, and pyrite	354.55
Slime, containing Sn, WO ₃ , and Bi	66.95
Bismuth ore, hand-picked	26.80
Wolframite, hand-picked	3.25
Tin ore	0.05
Total concentrates	1273.60

The development footage during this period, including sinking, driving, and raising, totals 11,877½ feet.

Registration of Engineers

*Because of widespread and persistent interest in the subject of licensing or registering engineers, architects, and surveyors, Engineering Council, at its meeting of October 25, 1918, authorized the creation of a committee to make a thorough study and submit a report. Fifteen engineers from all parts of our country, and of long experience in the various branches of the profession of engineering, were appointed as members of this committee. After fourteen months of work, the committee presented a report to Engineering Council at its meeting December 18, 1919. This report is accompanied by a "recommended uniform registration law, to regulate the practice of professional engineering, architecture, and land surveying". Council voted to receive this report and to give it immediately, together with the proposed law, as wide publicity as could be secured with the aid of the engineering and architectural societies, and the technical journals, in order that the members of these professions might be informed and discussion elicited to guide Council in the consideration of this important matter at its meeting in February 1920. Engineering Council has as yet taken no action upon the merits of the question of the advisability of legislation providing for the registering or licensing of practitioners of the professions named.

The first work of the committee was to investigate the general subject and to collect, so far as possible, available material bearing upon the subject in hand, including opinions from many engineers as to the need or desirability of legislation, as well as copies of all State laws passed and proposed, having to do with licensing or registration of engineers, architects, and surveyors. This preliminary investigation disclosed that very pronounced views were held by engineers throughout the country, both for and against State licensing or registration. The general sentiment one year ago was more opposed to such measures than it is today. The older members of the profession did not as a rule favor licensing, nor did they feel there was need for State regulation of engineering practice, while among the younger men there was a feeling that licensing or registration by the States would add prestige to professional engineers and in many ways benefit the profession, as well as individual engineers.

The advantages claimed for State licensing or registration are the same as those presumably gained by the laws regulating the professions of law and medicine, namely, that those who are incompetent and unqualified professionally to practise are unable to obtain certificates or licenses, and hence both the public and the profession are protected. On the other hand, those engineers who have already attained to recognized professional standing

feel that they not only do not need the benefits claimed for such legislation, but also they fear that State licenses or certificates of registration are apt to put the seal of State endorsement on men who do not deserve it, and that the public would assume that a licensed or registered engineer was thereby certified by the State as fully qualified, regardless of what might or might not be the requirements demanded before a license or certificate was granted.

However, the question has gone beyond the stage of debate, for already ten States† have enacted laws licensing or registering engineers, and other States are certain to enact similar laws during the present or coming sessions of their legislatures. In addition to these ten laws governing engineering practice, there are at least six States that require the licensing or registration of land surveyors and in at least eighteen States,‡ laws have been passed licensing or registering architects. Some of these ten laws are so drawn as to include both engineers and surveyors and some include engineers and architects and one or two include engineers, architects, and surveyors. Moreover, these laws are not at all uniform and in several instances are likely to prove seriously embarrassing and annoying to engineers whose activities extend beyond the limits of a single State. Because of the nature of professional engineering work the practice of an engineer frequently extends over several States and therefore it is vitally important, if there are to be State regulations for engineering practice, that these regulations be made uniform so far as possible and that the engineering profession unite in wisely directing such legislation.

Unfortunately, some of the laws for licensing architects have been so drawn as seriously to interfere with legitimate engineering practice, and the 'model law' proposed and advocated by the American Institute of Architects contains definitions of architecture and building which, should such laws be passed and enforced, would prevent anyone but a registered architect from planning or supervising the construction of any structure or any of the appurtenances thereto; consequently under this head would come a structure having simply foundations and girders, whether with or without appurtenances. This matter thus becomes of vital importance to mechanical, electrical, sanitary, and mining engineers, as well as to structural engineers.

The committee made a careful study of definitions for 'engineer', 'engineering', 'architect', and 'architecture', but it was found that any definitions for engineering

†Colorado, Florida, Idaho, Illinois, Iowa, Louisiana, Michigan, Nevada, Oregon, Wyoming.

‡California, Colorado, Florida, Idaho, Illinois, Louisiana, Michigan, Montana, New Jersey, New York, North Carolina, North Dakota, Oregon, Pennsylvania, South Carolina, Utah, Washington, Wisconsin.

*Abstract of the report of the committee as submitted to Engineering Council.

would be so general as to include too much, or too specific to be sufficiently general, or too voluminous to be suitable to incorporate in a law. Some have endeavored to include in a definition of "engineering practice" all sorts and kinds of construction work, but engineering includes investigations as well as plans and no catalogue can well be prepared sufficiently detailed to include all sorts of engineering activities. Both engineering and architecture are broad terms involving construction, and necessarily there can be no sharply-drawn distinction. Architects in the broadest sense are engineers, even if usually architecture is associated with ideas of artistic or decorative features. Land surveying does not involve matters that would ordinarily jeopardize life and health, but property rights are vitally affected by land surveying, and many States have deemed it essential to place restrictions and safeguards about the practice of land surveying. Land surveying is associated with both engineering and architectural practice.

This committee therefore deemed it advisable and to the best interests of all concerned to include in one law provisions for the registration of engineers, architects, and land surveyors. It recognizes that the practices of engineering and architecture overlap in many instances, especially in connection with the larger projects of modern structures, where many branches of the arts and sciences are combined, involving architecture, structural, mechanical, electrical, sanitary, and other lines of engineering.

In fixing the qualifications for registration in the proposed bill, these were purposely made high, but they have not been made unnecessarily difficult for reasonably competent men to meet. It is not intended that candidates would ordinarily be subjected to written examinations, but rather that the board of registration would pass upon the sufficiency of the professional record of each candidate. Minimum qualifications have been clearly set forth which must be met. In order to enable the Board to pass upon candidates fairly, certain qualifications are specified as "prima facie evidence of fitness", which (unless other facts derogatory to a candidate are also in evidence) will permit the Board to pass the candidate.

This "prima facie evidence" is not required, but if the candidate can present such evidence his application is the more readily passed upon. For instance, a candidate need not be a graduate of a college of engineering or architecture, but if he is, it is to his advantage. Likewise a candidate need not be a full member of one of the national technical societies or institutes, but if he has won such full membership it is greatly to his professional advantage.

The salient points of the bill, as recommended by the committee for adoption by each State, follow. These are necessarily somewhat condensed, but the matter omitted mainly involves the operation of details, and does not affect the principles involved:

Title: An Act to regulate the practice of professional engineering, architecture, and land surveying.

Section 1: In order to safeguard life, health, and property, any person practising or offering to practise professional engineering, architecture, or land surveying in this State shall hereafter be required to submit evidence that he or she is qualified so to practise, and shall be registered as hereinafter provided, and from and after months after this Act becomes effective it shall be unlawful for any person to practise or to offer to practise professional engineering, architecture, or land surveying in this State, unless such person has been duly registered under the provisions of this Act.

Section 2: Nothing in this Act shall be construed as requiring registration for the purpose of practising professional engineering, architecture, or land surveying by an individual, firm, or corporation on property owned or leased by said individual, firm, or corporation unless the same involves the public safety or health.

Note: Obviously no modern agriculturist should be prohibited from laying out and building the ditches or roads on his farm, or planning and building his own barn.

Section 3: To carry out the provisions of this Act there is hereby created a State Board of Registration for professional engineers, architects, and land surveyors hereinafter called the "Board", consisting of seven members, who shall be appointed by the Governor within sixty days after this Act becomes effective. At least three members shall be professional engineers, and at least three members shall be architects. Not more than one member of said Board shall be in the same branch of the profession of engineering. The Governor may remove any member of the Board for misconduct, incompetency, or neglect of duty. Vacancies in the membership of the Board, however created, shall be filled by appointment by the Governor for the unexpired term.

Section 4: Each member of the Board shall be a citizen of the United States and a resident of this State at the time of his appointment. He shall have been engaged in the practice of his profession for at least ten years and shall have been in responsible charge of work for at least five years. He shall be a member in good standing of a recognized society of professional engineers or architects, and except as provided in Section 5, shall be a registered professional engineer or a registered architect.

Section 5: Each member of the Board shall receive a certificate of appointment from the Governor, and before beginning his term of office he shall file with the Secretary of State the constitutional oath of office. The Board or any committee thereof shall be entitled to the services of the Attorney General, in connection with the affairs of the Board, and the Board shall have power to compel the attendance of witnesses, may administer oaths, and may take testimony and proofs concerning all matters within its jurisdiction.

Section 6: The Board shall hold a meeting within thirty days after its members are first appointed, and thereafter shall hold at least two regular meetings each year. Special meetings shall be held at such times as the by-laws of the Board may provide. A quorum of the

Board shall consist of not less than two engineer and two architect members.

Section 7: The secretary of the Board shall receive and account for all moneys derived from the operation of this Act and shall pay them to the State Treasurer, who shall keep such moneys in a separate fund. All expenses certified by the Board as properly and necessarily incurred in the discharge of its duties, including authorized compensations, shall be paid out of said fund.

Note: The administration of the law is made ultimately self-supporting. The legislature is not expected to appropriate money to accomplish the results contemplated.

Section 8: The Board shall keep a record of its proceedings and a register of all applicants for registration showing for each, the date of application, name, age, educational and other qualifications, place of business and place of residence, whether or not an examination was required and whether the applicant was rejected, or a certificate of registration granted, and the date of such action. A roster showing the names and places of business and of residence of all registered professional engineers, architects, and land surveyors shall be prepared by the Secretary of the Board during the month of of each year; such roster shall be printed by the State out of the fund of the Board as provided in Section 7, and a copy mailed to and placed on file by the clerk of each incorporated city, town, and county in the State.

Section 9: The Board shall, on application therefor, on prescribed form and the payment of a fee of dollars, issue a certificate of registration.

Note: The application required should include a complete statement of an applicant's education and a detailed summary of his technical work. The statements made should be under oath, and should be supported by the recommendations of not less than two professional engineers, architects, or land surveyors as vouchers.

1. To any person who submits evidence satisfactory to the Board that he or she is fully qualified to practise professional engineering, architecture, or land surveying; or

2. To any person who holds a like unexpired certificate of registration issued to him or her by proper authority in any State or Territory of the United States, or in any Province of Canada, in which the requirements for the registration of professional engineers, architects, or land surveyors are of a standard satisfactory to the Board;

Provided, however, that no person shall be eligible for registration who is under twenty-five years of age, who is not a citizen of the United States or Canada, or who has not made declaration of his or her intention to become a citizen of the United States, who does not speak and write the English language, who is not of good character and repute, and who has not been actively engaged for six or more years in the practice of professional engineering, architecture, or land surveying of character satisfactory to the Board. However, each year of teaching, or of study satisfactorily completed, of engineering or architecture in a school of engineering or architecture of

standing satisfactory to the Board, shall be considered as equivalent to one year of such active practice.

Note: The functions of the Board are largely administrative and judicial. The burden of presenting evidence of qualification is placed upon the applicant. The Board may in doubtful cases give technical examinations; but the clear intent is to utilize other State agencies, as for instance the engineering or architectural schools, to submit as evidence the results of examinations, with recommendations as to competency.

Unless disqualifying evidence be before the Board, the following facts established in the application shall be regarded as 'prima facie evidence', satisfactory to the Board, that the applicant is fully qualified to practise professional engineering, architecture, or land surveying.

Note: When the law goes into effect a large percentage of practising engineers, architects, and land surveyors will be registered to preserve the *status quo*. Long-continued practice, graduation from a technical school of approved standing with subsequent years of practice, or membership in high-grade technical societies, in the absence of disqualifying facts, is accepted as 'prima facie evidence' of qualification, as stated below.

(a) Ten or more years of active engagement in professional engineering, architecture, or land surveying work;

(b) Graduation, after a course of not less than four years, in engineering or architecture, from a school or college approved by the Board as of satisfactory standing, and an additional four years of active engagements in professional engineering, architecture, or land surveying work;

(c) Full membership in American Institute of Architects, American Society of Civil Engineers, American Institute of Chemical Engineers, American Institute of Electrical Engineers, American Society of Mechanical Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Naval Architects and Marine Engineers, or such other national or State engineering or architectural societies as may be approved by the Board, the requirements for full membership of which are not lower than the requirements for full membership in the professional societies or institutes named above.

Applicants for registration, in cases where the evidence originally presented in the application does not appear to the Board conclusive or warranting the issuance of a certificate, may present further evidence which may include the results of a required examination, for the consideration of the Board.

Note: The standard of qualification is set high for two reasons: The public welfare will be better promoted by maturer competency; and the prestige attaching to the term 'Registered' will be more significant for the professional men themselves. In requiring the younger, less experienced men to serve somewhat longer as assistants or understudies to older men, no hardship is imposed which will not be compensated by the fuller return in recognition when registration is achieved.

In determining the qualifications of applicants for registration as architects, a majority vote of the architect members of the Board only, shall be required; and in determining the qualifications of applicants for registration as professional engineers or land surveyors, a majority vote of the engineer members of the Board only, shall be required.

Note: The acceptance for registration of engineers by the engineers on the Board, and of architects by the architects on the Board, places the judicial finding of fitness or unfitness in the hands of those best qualified to judge. In administrative matters and in the revocation of certificates, the Board acts as a unit.

In case the Board denies the issuance of a certificate to an applicant, the registration fee deposited shall be returned by the Board to the applicant.

Certificates of registration shall expire on the last day of the month of following their issue or renewal and shall become invalid on that date unless renewed. The failure on the part of any registrant to renew his certificate annually in the month of shall not deprive such person of the right of renewal thereafter, but the fee shall be increased 10% for each month or a fraction of a month that payment for renewal is delayed, provided, however, that the maximum fee for a delayed renewal shall not exceed twice the normal fee.

Note: The amount of the fee to be paid by a registrant must be established by each State in the light of the number of fees to be expected, and the cost of administration.

Section 10: The Board shall have the power to revoke the certificate of registration of any professional engineer, architect, or land surveyor registered hereunder who is found guilty of any fraud or deceit in obtaining a certificate of registration or of gross negligence, incompetency, or misconduct in the practice of professional engineering, architecture, or land surveying. Any person may prefer charges of such fraud, deceit, negligence, incompetency, or misconduct against any professional engineer, architect, or land surveyor registered hereunder; such charges shall be in writing and sworn to by the complainant and submitted to the Board. Such charges, unless dismissed without hearing by the Board as unfounded or trivial, shall be heard and determined by the Board within three months after the date on which they are preferred. A time and place for such hearing shall be fixed by the Board. A copy of the charges, together with a notice of the time and place of hearing, shall be legally served on the accused at least thirty days before the date fixed for the hearing, and in the event that such service cannot be effected thirty days before such hearing, then the date of hearing and determination shall be postponed as may be necessary to permit the carrying out of this condition. At said hearing the accused shall have the right to appear personally and by counsel and to cross-examine witnesses against him or her and to produce evidence and witnesses in his or her defense. If after said hearing five or more members of the Board vote in favor of finding the accused guilty of any fraud or deceit in obtaining a certificate or of gross negligence,

incompetency, or misconduct in the practice of professional engineering, architecture, or land surveying, the Board shall revoke the certificate of registration of the accused.

The Board may re-issue a certificate of registration to any person whose certificate has been revoked, provided five or more members of the Board vote in favor of such re-issue for reasons the Board may deem sufficient.

The Board shall immediately notify the Secretary of State and the clerk of each incorporated city, town, and county in the State of its findings in the case of the revocation of a certificate of registration or of its re-issuance of a revoked certificate of registration.

Note: Revocation is recognized as a serious procedure in its effect on professional reputation, and the right of hearing and contest is recognized and provided for.

Section 11: The issuance of a certificate of registration by this Board shall be evidence that the person named therein is entitled to all the rights and privileges of a registered professional engineer, registered architect, or registered land surveyor while the said certificate remains unrevoked or unexpired.

Each registrant hereunder shall upon registration obtain a seal of the design authorized by the Board, bearing the registrant's name and the legend "registered professional engineer", or "registered architect", or "registered land surveyor". Plans, specifications, plats, and reports issued by a registrant may be stamped with said seal during the life of registrant's certificate, but it shall be unlawful for anyone to stamp or seal any documents with said seal after the certificate of the registrant named thereon has expired or has been revoked unless said certificate has been renewed or re-issued.

Section 12: Any person who after this Act has been in effect months is not legally authorized to practise professional engineering, architecture, or land surveying in this State according to the provisions of this Act and shall so practise, or offer so to practise in this State, except as provided in Section 13 of this Act, and any person presenting or attempting to file as his own the certificate of registration of another, or who shall give false or forged evidence of any kind to the Board, or to any member thereof, in obtaining a certificate of registration, or who shall falsely impersonate any other practitioner, of like or different name, or who shall use or attempt to use an expired or revoked certificate of registration, shall be deemed guilty of a misdemeanor and shall for each such offense of which he is convicted be punished by a fine of not less than one hundred dollars (\$100) nor more than five hundred dollars (\$500), or by imprisonment for three months, or by both fine and imprisonment. However, nothing in this Act shall be construed as excluding any registered architect from the practice of professional engineering or as excluding any registered professional engineer from the practice of architecture.

Note: By reason of overlapping of the fields of engineering and architecture, a clear line of demarcation cannot be made between these two professions. As this Act does not prohibit a chemical engineer from building a

steel arch bridge, it appears inconsistent to prohibit an architect from building such a bridge, or a structural engineer from building a church. Ethical considerations and professional opinion must confine the scope of each person's practice to the fields in which he is a master.

Section 13: The following shall be exempted from the provisions of this Act:

1. Offering to practise in this State as a professional engineer, architect, or land surveyor, by any person not a resident of and having no established place of business in this State.

Note: A professional card in a journal of national circulation is an "offer to practise" in any State in the Union. It would be manifestly unfair to compel a professional man to register in every State in which he may in this way, or by letter or otherwise, express his readiness to accept an engagement.

2. Practice as a professional engineer, architect, or land surveyor in this State by any person not a resident in this State and having no established place of business in this State, when this practice does not aggregate more than fifteen days in any calendar year; provided, that said person is legally qualified for such professional service in his own State or country.

Note: It is a distinct advantage to the people of any State to be able to call in for consultation a specialist from any other State. Such practice may be brief and often of an emergency nature.

3. Practice as a professional engineer, architect, or land surveyor in this State by any person not a resident of and having no established place of business in this State, or any person resident in this State, but whose arrival in the State is recent; provided, however, such a person shall have filed an application for registration as a professional engineer, an architect, or a land surveyor and shall have paid the fee provided for in Section 9 of this Act. Such exemption shall continue for only such reasonable time as the Board requires in which to consider and grant or deny the said application for registration.

4. Engaging in professional engineering, architecture, or land surveying as an employee of a registered professional engineer, a registered architect, or a registered land surveyor, or as an employee of a professional engineer, architect, or land surveyor, authorized by paragraphs 2 and 3 of this section, provided that said practice may not include responsible charge of design or supervision.

5. Practice of professional engineering, architecture, and land surveying solely as an officer or as an employee of the United States.

6. Practice of professional engineering, architecture, or land surveying solely as an employee of this State or any political subdivision thereof, at the time this Act becomes effective and thereafter only until the expiration of the then existing term of office of such employee.

Section 14: A corporation or partnership may engage in the practice of professional engineering, architecture, or land surveying in this State, provided the person or

persons connected with such corporation or partnership in charge of the designing or supervision which constitutes such practice is or are registered as herein required of professional engineers, architects, and land surveyors. The same exemptions shall apply to corporations and partnerships as apply to individuals under this Act.

Section 15: One year after this Act goes into effect, neither the State nor any county, township, city, town, or village, nor other political subdivision in the State, shall engage in the construction or maintenance of any public work involving professional engineering or architecture for which the plans, specifications, and estimates have not been made by, and the construction and maintenance supervised by, a registered professional engineer, or a registered architect; provided, that nothing in this section shall be held to apply to such public work wherein the contemplated expenditure for the completed project does not exceed two thousand dollars.

Section 16: Land surveying as covered by this Act refers only to surveys for the determination of areas or for the establishment or re-establishment of land boundaries and the subdivision and platting of land. Nothing in this Act shall be construed as prohibiting registered professional engineers or registered architects from making land surveys where such surveys are essential to engineering or architectural projects.

Section 17: All laws or parts of laws in conflict with the provisions of this Act are hereby repealed.

THE FUEL SUPPLY for the Province of Ontario comes largely from the United States. In the fiscal year ending March last the value of the coal and coke exported into Canada was \$79,000,000, and two-thirds of it was consumed in Ontario. For the previous fiscal year the actual tonnage of coal imported into the Province was 16,250,000, out of a total for the entire Dominion of 21,649,000 tons. The industries of Ontario have frequently suffered from interruptions arising from labor and transportation difficulties, and the serious nature of these interruptions forced itself on the attention of the public during the War, when the supply of the much-needed munitions, 53% of which was produced in Ontario, was limited through this cause. Fear of the recurrence of such conditions and apprehension as to the supply of fuel for domestic purposes gave rise to more active efforts for the utilization of local sources of fuel. Although Canada as a whole has coal resources greater than those of any country in the world with the exception of the United States, the mines are farther from the industrial centres of Ontario than are the coalfields in neighboring States. Ontario has, however, large beds of peat, the commercial uses of which have been investigated by Government experts, and they are now able to report practical results. It has been determined that peat can be used in combination with coal; and while it will not take its place, it promises to reduce dependence on imported fuel. Tests made at Alfred, Ontario, indicate that peat ready for use can be supplied at \$3.50 per ton at that point.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

DEVELOPMENT BY THE COPPER QUEEN COMPANY AT BISBEE.

DOUGLAS.—Local stockholders in the Heffern Gold Mining & Milling Co., owning properties in the Leslie Canyon district of the Swisshelm mountains, 25 miles north of here, are awaiting decision in the case of the 'Administrator of the Estate of Albert Heffern, deceased, v. the Heffern Gold Mining & Milling company et al'. The suit sought to foreclose a mortgage of \$10,000 alleged to have been voted by Heffern to himself as

\$50,000. The main shaft, now down 885 ft., will be continued to the 1200-ft. level and before reaching that point there is reason to believe the high-grade copper ore which is being sought will be found. The Copper Queen smelter here produced approximately 8,000,000 lb. of fine copper during January. Calumet & Arizona production was approximately 5,085,000 pounds.

BISBEE.—The annual report of the Employees Benefit Association of the Phelps Dodge Corporation, Copper Queen branch, for the year 1919, has been made public,

SMELTING PLANT OF THE CALUMET & ARIZONA MINING CO., AT DOUGLAS, ARIZONA

majority stockholder in the concern. The defence sets up the plea that although Heffern owned and controlled a majority of the stock he was in duty bound as an officer in the company to safeguard the interests of minority stockholders. The Heffern property contains several thousand feet of work in tunnels and shafts and is said to have a considerable amount of gold ore of milling-grade developed. Practically all of the stockholders are Cochise county people.

E. Frank Jones upon returning here from a month's visit to the United Arizona mine, situated near Mayer, Yavapai county, announced that the mine was about to be re-opened. Much of the stock is held in this district. Mr. Jones said that reputable engineers who had examined the property recently had rendered a favorable report and New York operators who hold the controlling interest had decided to finance the mine to the extent of

This association pays benefits for such injuries or sickness as is not covered by the State's compensation law, namely, for minor accidents, and sickness or death from natural causes. There was a total of 542 accidents of minor nature among the men employed in the mines of the Corporation here during the last year, for which \$6046 was paid in claims, an average of \$11 per claim. There were 68 accidents among men off duty for which \$3234 was paid in claims, an average of \$47 per claim. The State compensation law does not apply to men injured when off duty, so these figures include both serious and minor injuries. There were 737 cases of sickness among employees for which \$26,847 was paid, an average of \$36 in each individual case. Of the white employees of the Phelps Dodge Corporation, 82.8% were members of the association in 1919, while of the Mexicans but 7.1% held membership. The company contributed \$13,958 to the

fund, while the employees themselves contributed directly \$59,529 during the year.

Development and mining operations in the Copper Queen holdings in this district may be briefly stated as follows: Preparations are being made in the Czar division to prospect a large area of practically unexplored ground. About 1000 ft. of pipe is being laid for water and air-lines to be used in driving two drifts on the 200-ft. level. One of these will be driven under the first Copper Queen working in the old "glory hole", at which point high-grade ore outcropped on the surface and was mined on an incline. Original maps of this section of the company workings date back to 1881. The other drift will be driven under the old workings, to the west of the glory hole. Both drifts will be carried to the Dividend fault. Besides having prospecting value themselves, they will serve as points from which to prospect territory farther to the west. The new Southwest shaft has been raised from the fifth to the third level, a distance of approximately 200 ft. Work will be continued from this point to connect with work that has been done from the seventh level and from there will proceed to the surface, emerging near the top of Queen hill, between the Southwest change room and Uncle Sam shaft. The new shaft will possess many advantages over the present one which has but a single compartment equipped with underground hoist and is situated a long distance from the change room and waste dumps. Abandonment of the old shaft will make possible the mining of a large body of ore which cannot be touched at present because it lies in the pillar of ground around the shaft which must be left undisturbed as long as the shaft is in use. Drifts on the Gardner 800, 900, and 1000-ft. levels, and on the Sacramento 1100-ft. level are in the ore. Several hundred feet of development work is being done each month to determine the extent of the orebody. Owing to its high silica-content this ore is greatly in demand at the smelter for converter lining. The new winze of the Sacramento division has been sunk to a depth of about 100 ft. below the 1600-ft. level. Sinking will be continued until the 1800-ft. level has been reached, when drifting to the Dallas shaft will be started.

COLORADO

ACTIVITY AT SILVERTON.

CRIPPLE CREEK.—At the annual meeting of the stockholders of the Golden Cycle Mining & Reduction Co., held at Colorado Springs last week, the former board, including A. E. Carlton, L. G. Carlton, Spencer Penrose, Richard Rodolfs, Irving T. Snyder, E. P. Shove, and H. McGarry, was re-elected. The officers will be chosen on February 23 by the directors. The company last year paid 12 monthly dividends of 3c. per share, amounting to \$540,000. A similar dividend was paid on January 10, and the second distribution for 1920 will be made on February 10.

The Main shaft on the Battle mountain property of the Rose Nicol Gold Mining Co. has been sunk to a depth of 1200 ft. by the Reva Gold Mining Co., lessee, and a

station is now being cut preparatory to cross-cutting to the vein, encountered in sinking. Rich ore was obtained from the vein dipping through the shaft and it is hoped a good shoot will be developed.

The northern extension of the rich Maloney vein has been cut at the fifth level of the Empire State shaft of the Isabella company on Bull hill, by Ed Lindsey, lessee. Two cars shipped to date netted between \$30 and \$40 per ton. A. M. Colgin and Denver associates are installing an electric hoist and compressor at the Red Bird mine, on the south-western slope of Gold hill, just beyond the city limits. It is planned to sink the Red Bird shaft deeper and explore the Sherman and Yellow Bird claims adjoining through the Red Bird shaft.

The Caledonia on the southern spur of Gold hill, formerly owned by the late W. S. Stratton and sold by him to a London syndicate, and now owned by R. E. Dolan, of Mineral, Virginia, is again to become active under lease. The mine produced about \$200,000 from shallow workings, before its sale to the Britishers, but never paid expenses while under the English management.

LEADVILLE.—With railroad service restored, shipments are being made from the Hilltop mine at the head of Iowa gulch and on the Park county side of the line. At the present time about 25 tons of silver-lead ore is being hauled daily by team to Fairplay and thence shipped to the Leadville smelter of the A. S. & R. company. A considerable orebody has been opened up and is under development. The vein was found at a depth of 540 ft. and has been proved by drifting for 300 ft. It is said to average 12 ft. in width.

Two cars daily of iron-silver ore is shipped by the Down Town Mines Co. to local smelters. The ore contains some copper, lead carbonate, and zinc oxide. The company has about 120 men on the payroll and is doing extensive exploration work, in addition to current shipping.

As a sequel to the decision of Judge Hersey in the district court over the locus of the line between Lake and Summit counties, there is talk of the removal of one of the big molybdenum mills near Climax across the newly-defined line into Summit county to escape the heavy taxes that prevail in Lake county. This action is proposed by the American Vanadium Co., which has taken over the holdings of the Climax Molybdenum Co.

LAKE CITY.—L. T. Leach and his associates in Indianapolis are making progress in the development of their claims 14 miles from here. They hold 29 claims, partly developed by tunnels, from which they have shipped several carloads of gold-silver ore. Equipment and buildings have been provided for additional work.

SUMMIT COUNTY.—The Wellington mine is producing more zinc than any other property in the State. Two mills are kept running three shifts and 110 men are on the payroll.

SILVERTON.—Production is now on the upward trend, as the Sunnyside is speeding up on milling operations, and all of the mines are increasing their output. The Gold King Extension Mines Co. has opened up good mill-

ing-ore that promises profitable treatment. In addition, a development that promises well for future operations is the recovery of the famous 'Lost Stope'. During the operations of 1908, a cave on the Davis vein, between the No. 3 and 1 levels, resulted in the loss of a large stope containing over 10,000 tons of broken ore and a large block still in position. In the hope of relocating this stope an exhaustive survey of the workings was made during the period that the mine was closed down, which successfully placed the position of the stope, and its recovery is expected. The ore-shoot is 10 ft. wide and 200 ft. long, and the ore averages \$20. The Gold King is now shipping about a car per week of concentrate by way of Silverton. There is some prospect of the re-opening of the Gladstone branch of the railroad, as the weather of the past few weeks has resulted in rapid melting of the snows.

MICHIGAN

SMALL PROFITS IN LAKE SUPERIOR REGION.

Houghton.—January production of copper from the mines of the Lake Superior district showed practically no increase over the output in December, and there is not likely to be any substantial increase at any of the mines during the year, judging from the present outlook and in view of the labor situation. There is no prospect at this time of increasing labor forces and many of the mines of the district actually are operating at a loss. Very few are earning their dividends and practically none earned the amount disbursed to stockholders last year. Costs at the Ahmeek and Isle Royale were below

A MASS OF NATIVE COPPER IN A LAKE SUPERIOR MINE

18c., but this was not the case at any other property of the Calumet & Hecla and allied corporations. Neither the Osceola Consolidated, the Allouez, Centennial, La Salle, Superior, nor White Pine companies operated at a profit during the year.

The margin of profit at the Copper Range and the Quincy, both large producers, was closer than it has been for many years, and with depreciation charged in costs, the profit is wiped out. Ahmeek increased its output of ore for January, producing 64,125 tons, compared to 59,802 for December. From the old Osceola branch of

the Osceola Consolidated the output in January was 11,925 tons and from the Kearsarge 13,330, a total of 25,255. This is on a par with December. There was no appreciable difference in the average grade of ore mined at either property. Centennial produced 7,695 tons for January, which compares with 6,600 in December. Allouez increased slightly, securing 20,000 tons in January. Seven cars were shipped from the La Salle, all of it being from exploration work. Isle Royale showed a slight

AHMEEK STAMP-MILL

increase for January and, in addition to the operation of the Isle Royale mill during the entire month, shipped 8910 tons to the Osceola mill for treatment. Superior shipped no ore at all during the month.

Mayflower's drift on the vein is in 30 ft. at the present time. But one drift, that to the north, is going forward, and the exploration work is being watched with a great deal of interest. The shaft is bottomed at 1765 ft. in solid trap. The lateral is started at 1710 feet.

Hancock Consolidated this week cut No. 12 amygdaloid with a cross-cut on the 44th level. Drifting on the formation will start this week. At the point penetrated the lode was well mineralized and from the appearance it will be the equal of No. 3 lode, which is the richest vein opened east of the shaft. The Hancock is adding to its active underground force. Thirteen drills now are working regularly on two shifts, practically all in ore. Outside of No. 15 conglomerate the whole eastern territory is an enigma to the mining men who have examined it. The copper is found in what is probably a faulting of the Pwabic.

The following figures on cost of production at several mines in the Michigan copper district are approximately correct: Allouez, 21c.; Calumet & Hecla, 18c.; Isle Royale, 15½c.; Osceola, 20c.; Ahmeek, 16 cents.

NEVADA

DEVELOPMENT COMPANY'S PLANS.—PROTEST AGAINST DISCONTINUANCE OF BONDS BY TONOPAH MINERS.

GOLDFIELD.—The mill of the Development company will be treating 500 tons of ore daily by April 1, accord-

ing to A. I. D'Arcy, general manager. The mill-heads will be maintained at from \$15 to \$20 for a long period and the capacity will be increased gradually to 2000 tons as the higher-grade ore is exhausted. Thirty-seven of forty-five 50-ft. raises planned have been driven from the 380-ft. level of the Combination to tap the stope filling. Each raise has a capacity of 200 tons. Twelve thousand tons of ore assaying from \$12 to \$15 is broken in the Red Top. Production from the January mine will be started by blasting the edges of the glory-hole into chutes with an outlet on the 180-ft. level. The better grades of ore in all mines will be mixed with the lower grades to maintain a comparatively high average. The main south-east drift from the Combination shaft has been advanced a short distance over the Florence boundary line. Four raises will soon be started from near the face for the extraction of ore in the old Reilly lease block in the Florence adjoining the Combination. There is exposed in this block 25 ft. of \$16, 5 ft. of \$192, 5 ft. of \$236, and 7 ft. of \$300 ore, left by a lessee who was confident he would secure an extension of his lease after January 1 of this year. The higher grades will be shipped to a smelter. One of the raises recently driven in the Combination has opened 15 ft. of \$15 ore and another has opened 16 ft. of \$25 ore. In widening the junction of one of the three south-east haulage-ways on the 380-ft. level with the cross-cut to the main Development shaft, 9 ft. of \$12 ore has been found. It is planned to mine the January as rapidly as possible, as following this the Combination shaft can be abandoned and the 50 by 50-ft. block that protects the shaft can be taken. The net value of the ore in this block is estimated at \$200,000. Sampling for a length of 60 ft. and to a depth of from 10 to 15 ft. along the north-west side of the January glory-hole gave an average assay return of \$9.60. Inspection of the 280-ft. level of the Combination, in the heart of the material to be caved, shows the ground to be extremely heavy. The timbers are badly crushed and it is evident that the entire territory above the 230-ft., or the level at the top of the raises, is in ideal condition for caving. Exploration of the upper workings shows that the Consolidated company had mined to the limit of safety when work was stopped and that the impossibility of holding the ground economically for further mining was as much responsible for the suspension of operations as the shortage of good-grade ore.

DIVIDE.—According to unofficial reports, a winze being sunk from the 200-ft., or bottom, level of the Divide Extension is being continued from the present depth of 45 ft. in a 6-ft. width of \$600 gold-silver ore, the value of the former being twice that in silver. A drift is being driven west in the vein cut in the north cross-cut on the 200-ft. level of the Victory. The width of the vein, according to the management, "probably is 11 ft." and the value of the ore remains the same as when the shoot was entered in the cross-cut. Shipments from the Tonopah Divide average 25 tons of \$40 ore daily, showing that the output is maintained at a minimum. This is due largely to the limited capacity of the MacNamara mill.

TONOPAH.—E. P. Cullinan, president of the Dividend, in the Divide district, stated a few days ago that the Dividend company would continue to pay a 50-cent wage bonus, disregarding the action of other operators in Tonopah and Divide in discontinuing payment of the bonus. The Tonopah Trades Assembly has protested to the mine operators association against the announced discontinuance of the wage bonus. An increase in prices at the commissary since it was opened is given as the reason for the protest.

OREGON

OPERATIONS RESUMED AT QUEEN OF BRONZE PROPERTY.

WALDO.—A general resumption of copper mining in this district seems probable. Several producing copper mines, which closed down on the suspension of hostilities last November, had shipped ore containing more than 12% copper to the Tacoma smelters, while lower-grade material accumulated on the dumps. It was during the war-period that the smelter operators discovered that the southern Oregon copper ores could be used to advantage as a flux for Alaskan copper ores, and with the smelter in the market for such ore several companies are planning to resume operations. The Blue Ledge copper mine in the Upper Applegate district, just over the line in California, was the only mine in this region to continue shipments after the Armistice. This mine has been operating steadily with a crew of 25 miners, shipping three cars of ore per week.

Work at the Queen of Bronze and associated properties has recently been resumed under lease, and regular shipments are being made. This property is $2\frac{1}{2}$ miles east and south of Waldo and is equipped with a 100-ton smelter. The ore is hauled a short distance to the smelter. This plant has a 125-ton water-jacketed blast-furnace operated semi-pyritically, making matte, averaging 45% copper, 2.5 oz. silver, and \$2.50 gold per ton, that is shipped to the Tacoma smelter for converting. Up to 1910 more than \$150,000 was spent on the property, including the building of the smelter, and more than 20,000 tons of ore was smelted, the average content being 8½% copper and the usual amount of gold and silver. The ore contains massive chalcopyrite, pyrrhotite, and some pyrite, together with some oxidized minerals. It occurs in a brecciated zone of variable width, in which chunks of massive copper and iron sulphides are found.

BAKER.—The first dry-placer plant erected in Oregon was successfully operated during the past summer and fall. For many years it has been well known that exceptionally rich placers existed on the high bar or tableland near Baker, but the fact that no water was available rendered the property worthless, although, from time to time, it has been held by various locators, who have prospected the ground and 'packed' the gravel to water, with surprising results. Somewhat over a year ago, W. J. Meeker, of Portland, who had been investigating and making a study of dry concentration, began negotiating with the present owners, and finally obtained a lease, with purchase option. The owners, being skeptical as to pos-

sibility of working the deposit, insisted that suitable machinery or equipment for extracting gold be placed on the ground and successfully operated within a prescribed period of time. The equipment consists of a mounted steel drum, gas-engine for revolving same, a grizzly, wire-screen, feed-hoppers, concentrating table, gas engine to operate same, and a blacksmith-shop.

The drum is a disintegrator and dryer. The gravel fed into it is churned for a few minutes, then discharged over the grizzly. Small boulders, up to 8 in. diameter, are included in the charge to act as grinders. The material passing over the grizzly is cleaned as though washed in sluice-boxes; what goes over the grizzly is fed over a screen of $\frac{1}{2}$ or $\frac{3}{4}$ -in. openings to the concentrator, which is a table known as the Stebbins, made in Los Angeles. The first operation over the table reduces a cubic yard of ma-

Co. and Utah Consolidated Mining Co. were closed. The final arguments were not completed until late in the afternoon, when Judge Johnson announced that he would take the cases under advisement. Several of the attorneys connected with the companies involved expect a decision within sixty days.

BISBAM.—During 1919, the Utah Apex Mining Co. produced 51,538 tons of ore, from which was obtained 2257 oz. of gold, 195,715 oz. of silver, 11,753,984 lb. of lead, 7,671,742 lb. of zinc, and 386,833 lb. of copper, the gross proceeds of which amounted to \$23,888. During the year the company expended for labor and supplies \$655,098; salaries and similar items, \$12,787; State and local taxes, \$26,285; compensation insurance, \$17,055; reduction expense, \$305,817; transportation on ores, \$50,953, making total expenditures of \$1,097,996. There-

A DRY-PLACER PLANT IN OREGON

terial to approximately 15 lb. of concentrate. This, at the end of the day, or week, is re-treated on the concentrator, and thus further reduced 80 to 90% in bulk. In re-concentrating, the slope and speed of the table are changed. Among the natural advantages is the fact that there is little waste or over-burden to handle. Nowhere does this exceed 20 inches. It is expected that the present equipment will be replaced by a much larger plant this spring.

UTAH

MINE ACCIDENTS DURING 1919.—EUREKA ORE SHIPMENTS.

SALT LAKE CITY.—According to figures released by the Industrial Commission of Utah, nine miners and four employees working on the surface around metal mines were killed during the year 1919, as compared with a total of twenty-three during the previous year. Two men, other than employees, met death in the metal mines during 1919. At the mills and smelters of the State, five employees were killed during 1919, as compared with ten for 1918.

Following the final arguments of Adrian C. Ellis, attorney representing the Utah Consolidated, before Tillman D. Johnson, Judge of the United States District Court, on January 31, the cases of the Utah Apex Mining

Co. and Utah Consolidated Mining Co. were closed. The final arguments were not completed until late in the afternoon, when Judge Johnson announced that he would take the cases under advisement. Several of the attorneys connected with the companies involved expect a decision within sixty days.

ALTA.—Recent thaws have made it impossible for mines to ship ore by sleighs to the valley smelters. It was expected that the January output from the Emma silver mine would total \$40,000, but on account of weather conditions making the roads impassable, the output will be about \$28,000, according to George H. Dern, general manager. Approximately 300 tons, that should net \$40 per ton, await shipment at the mine. A recent shipment of ninety-four tons assayed 61 oz. silver, 9% lead, and 5% zinc and netted \$6866, while another later shipment of eighty-eight tons netted \$5532.

The annual meeting of the stockholders of the Sells Mining Co. was held at Salt Lake City on February 3. At this meeting more than 75% of the issued stock was represented, being a record in the history of the company. V. S. Snow was elected to the board of directors to suc-

ceed A. O. Jacobsen. Following the stockholders' meeting, the board of directors held a meeting and elected John Zink, president; John Gallacher, vice-president; W. H. Weyher, secretary and treasurer; and V. S. Snow and A. W. Joerger, directors. According to information given out by Mr. Weyher, a recent strike of ore in the property gave samples assaying \$14.50 in gold, 240 oz. silver, and 1% copper per ton.

GOLD HILL.—Shipments from the Western Utah Copper property during January totaled about 3750 tons. This is lead-silver ore that is being glory-holed. On the 700-ft. level, development is highly encouraging, and the vein on this level is 62 ft. wide. Changes are being made in the milling plant which will double its present capacity.

EUREKA.—Shipments of ore from this district for the week ending January 31 totaled 149, a decrease of 12 cars as compared with the previous week. The Chief Consolidated shipped 48 carloads; Dragon, 18; Tintie Standard, 15; Iron Blossom, 13; Eagle & Blue Bell, 12; Grand Central, 9; Colorado, 9; Centennial-Eureka, 6; Swansea, 4; Ridge & Valley, 4; Victoria, 3; Mammoth, 3; Sunbeam, 2; Alaska, 2; Tintie Mill (bullion), 1 car.

Excellent progress is being made in sinking the shaft at the property of the Pinion Queen, according to Edward Sutherland, manager. The work is being done under contract at the rate of five feet per day. The shaft has now reached a depth of 450 ft. and the porphyry through which it passes contains iron sulphides, with about \$7 per ton in gold and silver. It is the intention of the management to award another contract which will take the shaft from the 500-ft. level to the 800-ft. level, and it is believed that conditions at the latter point will be favorable for drifting. The Pinion Queen has made better time in sinking its shaft than any other property in the eastern part of the district, 450 ft. having been sunk since October 14.

Through a deal closed on January 31, Eastern interests have acquired control of the Addie Mining Co., whose property in the eastern part of the district consists of five patented claims. The property has had a small amount of development, consisting of a tunnel and two shafts. Work is to be started at once to clean out and re-timber the shafts, preparatory to further work.

During the past week the Tintie mill shipped a car containing 29 tons of bullion, the value of which is \$135,000. This shipment contained more silver and less copper than previous consignments, and is the richest bullion

ever produced at the mill, according to Theodore P. Holt. Ample ore is being secured to enable the company to operate its plant at maximum capacity, most of it coming from the Knight properties.

It is expected that by February 10 new equipment will be in operation at the property of the Independence Mining Co. so that sinking of the shaft can be resumed. This shaft now has a depth of 70 ft., and it is the intention to send it down to the 700-ft. level before undertaking any other development work. This property is north-east of the Tintie Standard. Recent developments in the northern part of the Tintie Standard property lead officials of the Independence to believe there is an excellent possibility of favorable results being obtained in the exploratory work they contemplate.

A new company, to be known as the Silver Star Consolidated, has been organized by residents of Silver City. This company will have thirty-three claims, which are south-east of Silver City. The officers are: William Mott, president; Samuel Werrett, vice-president; W. T. Hatch, secretary and treasurer; A. L. Daley and David Greenhaigh, directors.

BRITISH COLUMBIA

PRODUCTION FIGURES FOR 1919

VICTORIA.—On January 29, at the opening session of the Provincial Legislature, Milliam Sloan, Minister of Mines, announced the preliminary estimate of the metal production of British Columbia. As in several instances the figures differ materially from those published in the issue of December 27—lead, it will be seen being nearly double the amount given then—it is well to publish the official figures in full. In accounting for the great decrease of \$7,815,221, as compared with the value of the output of 1918, Wm. Fleet Robertson, Provincial Mineralogist, says: "This decrease in production, as compared with the preceding year, loses its adverse significance when it is considered that the 1919 production is materially greater than that of any year prior to 1916."

The official figures as included in the report are given in the table at the bottom of this page.

SLOCAN.—The Rambler-Cariboo Mines, Ltd., has made the final payment of \$25,000 on the Last Chance and Jennie claims, which were purchased last July. Since the claims were acquired, the No. 9 level has been extended 250 ft. into the Jennie claim from the Rambler-Cariboo mine, and a strong vein of good ore has been developed. The No. 8 level is within 35 ft. of the Jennie claim, and

British Columbia Metal Production During 1918 and 1919

	Quantity	Value	Quantity	Value	Increase	Decrease
Gold, placer, ounces	16,000	\$320,000	14,325	\$286,500	\$33,500
Gold, lode, ounces	164,674	3,403,812	141,769	2,930,365	473,447
Total gold		\$3,723,812		\$3,216,865	506,947
Silver, ounces	3,498,172	3,215,870	3,667,516	3,871,063	\$655,193

Copper, pounds	61,483,754	15,143,449	45,984,046	8,631,205	6,512,244
Zinc, pounds	41,772,916	2,899,040	43,694,583	2,717,893	181,237
Total		\$27,910,278		\$20,095,057	7,815,221

the ore at the face assays as much as 200 oz. of silver per ton. There are several inches of clean sulphide ore in the vein. The last shipment assayed 68% in lead and 139 oz. silver per ton. Three feet of high grade ore has been exposed between the 7th and 8th levels at the Queen Bess mine. This mine has produced more high grade than any other mine in the Clarence Cunningham group and the returns from it have largely provided funds for Mr. Cunningham's extensive operations. William Thomlinson has been elected president of the Sloam branch of the British Columbia Prospectors' Protective Association. Mr. Thomlinson has done much to improve the educational facilities for prospectors in the district.

STEWART.—The tunnel on the E Pluribus claim of the Big Missouri mine has struck ore showing native and ruby silver. J. R. McDonald, of New York, who bonded

should install a refinery. The explanation, it is thought, is that the company has American corporate affiliations that make such action impracticable. Hence it is maintained that the Government should take the initiative.

NELSON. J. R. Hunter, president of the Nelson Board of Trade, in his annual report in referring to the mining situation is quoted as saying:

"The Eureka and Granite Poorman mines have been bonded to Walla Walla capitalists, who are at present driving a long cross-cut on the Eureka with the object of striking the orebodies at greater depth. When this is done and shipping is commenced the ore will be treated at the Granite mill.

"The Molly Gibson has been under development and considerable shipping has been done. The Ivy Fern (Cultus creek) which has been bonded by the Consoli-

THE TRAMWAY OF THE BRITANNIA MINE, HOWE SOUND, BRITISH COLUMBIA

the Unicorn group last fall, has started a tunnel on the claim, notwithstanding the attending difficulties due to the severity of the weather. It is seldom that new work is started in this district in mid-winter. The Premier mine is keeping a continuous stream of ore running between the mine and tide water. The snow-tractors have proved to be a failure.

PRINCE RUPERT.—A delegation from Prince Rupert recently waited on members of the Provincial government, advocating the establishment of a metal refinery in British Columbia. Chief among the arguments in support of the petition is that of the necessity of doing everything possible to readjust the trade balance. With copper going out of the country for refinement to be repurchased in the finished manufactured article by Canada one serious obstacle to the removal of the present intolerant condition was apparent. The opinion is expressed that the Granby Consolidated Mining & Smelting Co., the greatest producer of copper in the Province,

dated Mining & Smelting Co. is being developed by the driving of a cross-cut tunnel to strike the main orebodies at depth. A great deal of surface work also is being done. This is going to be one of the high-tonnage properties of the Interior.

"We might also mention the Nugget, Motherlode, and the Emerald, the last having just completed a new mill for the treating of its ores. Its showings are most satisfactory and it no doubt will be one of the big producing properties."

ONTARIO

COBALT PRODUCES WELL IN JANUARY.

COBALT.—Preliminary estimates place the output of silver from Cobalt during January at 1,000,000 oz., valued at approximately \$1,250,000. The indications are that the number of producing mines in 1920 will exceed that of 1919. All the mines that contributed to last year's output are operating, and a number of smaller

enterprises are being added to the list. Chief among these will be the Bailey-Cobalt, in connection with which litigation has recently been settled, leaving open the way to active resumption of operations. By conservative engineers it is estimated to contain several thousand tons of comparatively high-grade ore.

The meeting of the shareholders of the Trethewey-Cobalt company, held January 30 in Toronto, endorsed the agreement recently entered into by the directors authorizing the sale of the Cobalt mine of the Trethewey company to the Coniagas Mines, Ltd., the price being \$100,000. The Trethewey retains a few extra mill parts for possible use at its Castle properties in the Gowganda district.

The Mining Corporation, in addition to its usual activity in searching for prospective mines, during the coming spring will carry out considerable exploration work on claims which the company acquired last fall in the township of Butt, the object being exploration for radium-bearing ore. Butt township is situated in the Nipissing district, south from North Bay, and about 150 miles from Cobalt. The erection of a 300-ton flotation plant on the Chambers-Ferland property is being considered, following the sampling of the tailing pile, by Toronto people who have for some weeks held an option to purchase the tailing.

At the 530-ft. level of the Beaver mine the new body of silver ore opened up early in the year has been found to be ten feet wide in places, the enrichment extending several feet back in the walls beyond the vein proper.

A new explosive, known as 'Thompsonite', is soon to be placed on the market at Cobalt, the head office and plant of the new concern being situated at Desoronto, Ontario. In a statement just sent out, the new explosive is referred to optimistically by the managers of the Beaver, Temiskaming, and Bourke's mines.

PORCUPINE.—The mines are steadily increasing their output as the influx of laborers has enabled them to take on more men. The Dome Mines is now treating about 1000 tons per day and is said to have succeeded in reducing working costs to about \$3 per ton. The workmen are preparing to make a demand before long for a substantial increase in wages, which are considerably below those paid at Cobalt. At present the Porcupine miners receive \$4 per day and upward, which is about \$1 less than the Cobalt scale including the bonus based on the selling price of silver. A decline in the price of silver to between 90c. and \$1 per ounce would make the wage scales about even. The Porcupine men emphasize the improbability of such a downward movement, and the demand for a readjustment is scheduled to take a definite shape in the early spring. So far there has been no indication of what action will be taken by the mining companies.

KIRKLAND LAKE.—At the Kirkland Lake mine the deposit of rich ore which is being developed has been found to be considerably larger than was previously known, drifts on the 400 and 500-ft. level having been extended. The orebody, about 5 ft. wide, maintains its grade, and

development work will be continued on the 600 and 700-ft. levels. The Lake Shore is on a normal basis of operation and work has been resumed at the 400-ft. level. The Wood-Kirkland has been organized with a capitalization of \$2,000,000, and has secured about 300 acres in this district, on which work will shortly be begun. The financial statement presented at the annual meeting of the Tough-Oakes showed a net loss for the year of \$105,934 owing to the interruption of operations by the miners' strike. Col. H. H. Johnson, general manager, now in Rhodesia, is expected to return in March, when it is proposed to resume operations.

LARDER LAKE.—The Associated Gold Fields reports that the opening up of Block 'C' has proved highly satisfactory. Diamond-drilling and underground workings at regular intervals for a length of 3500 ft. show that the orebody is nowhere less than 400 ft. wide, reaching to a width of 500 ft. in some places. Its known length on the company's properties is over one mile. Work is being pushed to enable the engineers to estimate the total gold content. On Block 'B' much free gold has been found in cross-cutting at the 400-ft. level. The company has now 150 men on the payroll and is increasing its force.

SONORA

RICH ORE AT NORTH TIGRE.—MILL AT ROY TO BE STARTED AGAIN.

NORTH TIGRE.—A five-foot vein of ore carrying a rich streak highly impregnated with native silver, assaying as high as 2000 oz. per ton, has been cut on the eighth level of this property operated by the North Tigre Leasing company. This is the richest ore yet found in the property, which is under lease to a group of Bisbee and Douglas people for a period of two and a half years. A 50-ton mill which has been in course of erection for several weeks is expected to make its first run about March 1. Approximately one and a quarter million dollars worth of ore has been blocked out in the workings, it is stated by the management. Frank J. Holmes, manager of the property, is superintending construction of the mill and breaking ore preparatory to starting the plant, which will include flotation and table concentration processes.

BIG FOUR.—John Hohstadt has let a contract to Macaro Alatore to run a tunnel 300 ft. on his Big Four property, approximately four miles from El Tigre. This is virgin ground, but it is Mr. Hohstadt's expectation that he will be able to develop a large vein of silver-gold-lead ore which crops out at the surface. The tunnel is expected to cut the vein a considerable distance below the surface.

ROY.—W. R. Maycumber, mill superintendent for the Roy mine at Pilares de Teras, recently purchased a large gasoline engine in Douglas to be used in operating the 50-ton flotation plant. Upon test runs made recently the mill was found to work well and make good recovery, but the engine was too small to operate the plant successfully. With the larger engine in place Mr. Maycumber believes the last obstacle to placing the Roy in the list of steady producers will have been removed. The property has large reserves of silver ore developed.

ARIZONA

Jerome.—Work on the new tunnel of the Shea mine is expected to commence February 1. A new road to the Shea camp has been completed. A compressor and electrical equipment for the same are to be installed at the portal immediately.

Kingman.—Messrs. Fay and Schoenmehl announced on their arrival at Kingman that sinking operations at the Bella Union mine are to be resumed immediately. The present shaft which is 125 ft. deep will be sunk to the 500-ft. level at which point drifting is to be done. Machinery is now being installed in the Dean mill. The late storms have delayed construction. The capacity of the plant will be 40 tons per day. Re-timbering of the shaft at the Daisell mine has been completed and sinking commenced at the 300-ft. level. This level is to be cleaned and drifting started. To meet the increased power requirements a 40-hp. Fairbanks-Morse engine has been ordered.

Miami.—The Van Dyke Copper Co. is to increase its sinking operations immediately, the single shift now working is to be increased to three shifts. The shaft is planned to go from the 600 to the 1500-ft. level.

Patagonia.—Messrs. Brown and Reed of the Flux Mining Co. have gone to Courtland to arrange the shipment of engine, compressor, drills, and miscellaneous machinery recently purchased.

Phoenix.—The Pluma Kings Mining Co. operating in the Vulture district for the past two years has opened paying lead, gold, and silver ore. The company intends to install equipment for larger development.

Tucson.—The San Xavier Copper Co. recently cut high-grade copper-silver ore in sinking the main shaft. Samples are said to run 12% copper and 15 oz. in silver. Ralph W. Langworthy who holds notes against the Mile Wide Copper Co. has made application in the Superior Court for the appointment of a receiver.

CALIFORNIA

Bakersfield.—The State Range Minerals Co. of Bakersfield, with mines in the State Range, has lately constructed a complete 50-ton milling-plant. Standard ball-mills, a gyratory crusher, two Overstrom concentrating tables, and K. & K. flotation machines are included in the equipment. Heretofore the ores from the mines have been shipped to the U. S. Smelting, Refining & Mining Co. at Salt Lake City. The ore averages \$35 per ton in silver, lead, and gold.

Redding.—The Noble Electric Steel Co. is shipping two carloads of iron per month from Heroult to various iron works in the State. Thirty-three carloads have been shipped since last July, the ore containing 65% iron.

COLORADO

La Plata.—J. H. Avery is shipping from the Idaho dumps and has good ore, assaying \$50 per ton in gold.

Ouray.—The rich silver-copper ore recently found on the Early Bird group is said to assay 30% copper in a 3-ft. vein. The tunnel is now in a distance of 170 ft., and the vein is widening. A pack train of 18 horses is hauling the ore to the railroads, and the force of miners is being increased to

thirty. Luna & Eckman are shipping steadily from the Wedge, having opened up high-grade silver ore averaging \$200 per ton.

Telluride.—The Tombay Gold Mines Co. is having some difficulty in making the desired separation of zinc, but the new milling process is giving a highly satisfactory recovery.

The Liberty Bell Gold Mining Co. has decided to continue operations, this decision being arrived at after a re-survey of the old vein. As the company had definitely decided to close down on February 1, all power contracts were dissolved, with the result that milling operations will not be resumed until such time as more power is available.

IDAHO

Coeur d'Alene.—The width of the new orebody in the property of the Consolidated Interstate-Callahan company, at Wallace, has widened to 22 ft. While generally referred to as 'new' this orebody is regarded as the continuance of a shoot that disappeared at a fault a year ago. The average content of the ore throughout its 22 ft. of width is 23.7% zinc, 12.8% lead, and 4 oz. of silver per ton, according to report.

MONTANA

Anaconda.—The fertilizer-plant, now under construction for the Anaconda company, at a cost of \$75,000, will have an initial capacity for the treatment of 50 tons of phosphate rock daily, but this will be increased to 1000 tons daily before the conclusion of the year. The company's product is known as a 'double acid' fertilizer and will contain about 80% phosphoric acid.

Butte.—The cross-cut on the 2700-ft. level of the Colorado mine of the Davis-Daly Copper Co. is cutting a number of high-grade stringers of glance and bornite ore, indicating a continuance of the mineralization.

Figures for January show that the North Butte company produced approximately 2,000,000 lb. of copper. This is almost three times December's output, when, owing to the incipient strike of soft-coal miners, the mines and smelters of Anaconda were compelled to close down. Ground now being passed through gives every indication that the Edith May vein will be cut on the 3400-ft. level. In this event, the next step will be to open another level 200 ft. below.

NEVADA

Tonopah.—It is reported that 60% of the miners at Tonopah have walked out following the refusal of the companies to continue the bonus of 50c. per day. About 600 men are affected.

The decision of most of the Divide companies not to cancel the bonus, marks a serious split in the ranks of the mine operators. Reports are current that several Tonopah operators plan to meet the demands of the men and restore the bonus as a flat wage increase.

UTAH

Park City.—For the week ending January 31, eight mines in this district shipped 2324 tons of ore, as compared with 2344 tons for the previous week. Of this tonnage, the Ontario shipped 757 tons; Silver King Coalition, 518 tons; Judge Mining & Smelting, 534 tons; Daly-West, 119 tons; Daly Mining, 110 tons; Naildriver, 165 tons; Silver King Consolidated, 110 tons; and the New Quincy, 11 tons.

STATEMENT BY MR. HOOVER

On January 8 Mr. Hoover issued the following statement in New York.

In order to answer a large number of questions all at once, let me emphasize that I have taken a day off from the industrial conference in Washington to come to New York solely to attend to pressing matters in connection with the children's relief. I want to say again: I have not sought and am not seeking the Presidency. I am not a candidate; I have no "organization". No one is authorized to speak for me politically.

As an American citizen by birth and of long ancestry, I am naturally deeply interested in the present critical situation. My sincere and only political desire is that one or both of the great political parties will approach the vital issues, which have grown out of the War and are new, with a clear purpose looking to the welfare of our people and that candidates capable of carrying out this work should be nominated.

If the treaty goes over to the Presidential election (with any reservations necessary to clarify the world's mind that there can be no infringement of the safeguards provided by our Constitution and our nation-old traditions) then I must vote for the party that stands for the league.

With it there is hope, not only of the prevention of war, but also that we can safely economize in military policies. There is hope of earlier return of confidence and the economic reconstruction of the world. I could not vote with a party if it were dominated by groups who seek to set aside our constitutional guarantees for free speech or free representation, who hope to re-establish control of the Government for profit and privilege.

I could not vote with a party if it were dominated by groups who hope for any form of socialism, whether it be nationalization of industry or other destruction of individual initiative. Both these extremes, camouflaged or open, are active enough in the country today. Neither of the dominations would enable those constructive economic policies that will get us down from the unsound economic practices which of necessity grew out of the War, nor would they secure the good will to production in our farmers and workers or maintain the initiative of our business men. The issues look forward, not backward.

I do not believe in more than two great parties. Otherwise, combinations of groups could, as in Europe, create a danger of minority rule. I do believe in party organization to support great ideals and to carry great issues and consistent policies. Nor can any one man dictate the issues of great parties. It appears to me that the hope of a great majority of our citizens in confronting this new period in American life is that the great parties will take positive stands on the many issues that confront us, and will select men whose character and associations will guarantee their pledges.

I am being urged by people in both parties to declare my allegiance to either one or the other. Those who know me, know that I am able to make up my mind when a subject is clearly defined. Consequently, until it more definitely appears what the party managers stand for, I must exercise a prerogative of American citizenship and decline to pledge my vote blindfold.

I am not unappreciative of the many kind things that my friends have advanced on my behalf. Yet, I hope they will realize my sincerity in not tying myself to undefined partisanship.

LOCAL SECTION A. I. M. & M. E.

The next meeting of the San Francisco Section will be held at the Engineers Club on February 24. Edwin Higgins will read a paper on "The Human Element in Mining". A number of engineers have been invited to take part in the discussion, which promises to be interesting and useful.

Personal

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

C. Erb Wunsch, of Golden, Colorado, is in New York.

G. W. Wood, manager for the Sunset Mining Co., at Leadore, Idaho, is at Salt Lake City.

S. M. Soupeoff, mining engineer of the Utah Department of the A. S. & R. Co., has returned to Salt Lake City after a trip to Arizona.

J. C. Ray has returned to Palo Alto from the Rice Lake gold-mining district in Manitoba and expects to go to New York this week.

Clarence Clyde has returned to San Francisco from Siam. While in the Malay States he met C. H. Munro, whom he reports well and cheerful.

J. Mackintosh Bell has returned to Almonte, Ontario, from Cambridge, where he delivered a course of geological lectures at Harvard University.

Sidney J. Jennings, vice-president of the U. S. Smelting, Refining & Mining Co., passed through San Francisco last week on his way from Utah to Arizona.

George A. Packard, of Boston, passed through San Francisco last week. He is examining mines in Nevada, California, and Arizona, and will return to Boston about March 15.

C. R. McCollom has lately returned from Army service in France, and has opened an office in the Consolidated Realty Bdg., Los Angeles, for the resumption of practice as mining engineer and field geologist.

H. C. Smith, who has been connected with the Utah Copper Co. for the past 14 years, the last six years being in the capacity of superintendent of the Magna plant at Garfield, has been promoted to the position of superintendent of mills for the Ray Consolidated Copper Co. at Hayden, Arizona.

Hjalmar E. Skongor has recently severed his connection with the Guggenheim Brothers, Chile Exploration Co., and Braden Copper Co., with whom he has been connected as their designing engineer for the past seven years, and has returned to private practice as consulting industrial engineer.

Obituary

Robert Hay Anderson died in Mexico City on December 23, 1919, at the age of 48. He was a Scot by birth and had spent most of his life as a mining engineer in Mexico. We record his death with deep regret, for he was a man of many engaging qualities and the most sterling character.

Alfred H. Peabody, age 54, died at his home in Salt Lake City on January 29, following a three days' illness of influenza-pneumonia. He was widely known in Utah, being secretary of the Judge Mining & Smelting Co., the Daly-West Mining Co., and the Park-Utah Mining Co., all in the Park City district. He was a talented musician, being organist at St. Marks Episcopal Cathedral and also at the Masonic Temple. He is survived by a wife and two sons.

J. T. Mills, one of the best known mining men in British Columbia, died recently. He came to the Province in 1900 from Montana and was one of the first interested in what is now the Britannia mine, on Howe Sound. Subsequently he became identified with the group of claims at Hidden Creek, which later developed into the Hidden Creek mines, operated by the Anxox branch of the Granby Consolidated Mining & Smelting Company.

THE METAL MARKET

METAL PRICES

San Francisco February 13

Aluminum dust, cents per pound	65
Antimony, cents per pound	12 00
Copper, electrolytic, cents per pound	19 25
Lead, pig, cents per pound	9 00 10 00
Platinum, pure, per ounce	\$135
Platinum, 10% iridium, per ounce	\$180
Quicksilver, per flask of 7 1/2 lb.	\$80
Spelter, cents per pound	10 50
Zinc dust, cents per pound	12 50-15 00

EASTERN METAL MARKET

(By wire from New York)

February 9.—Copper is dull and easier. Lead is quiet and steady. Zinc is inactive and lower.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1 01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (400 fine) in British currency is 46 1/2 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

Prospects of falling prices are discussed by the National Bank of Commerce in New York in the February number of 'Commerce Monthly', the bank's publication just issued. The bank, while not predicting a definite time when price adjustment may be expected, maintains that the process need not mean disruption to business.

"If, when the tide turns," says the bank, "readjustment is not too long resisted and production is not too much slowed down, and if the situation is flexible and competitive, we may expect to meet the reaction without disaster. The country is not as well braced now for reaction as it was at the time of the Armistice, but so many of our major industries are in an exceedingly strong position, and our banks are as a whole in such excellent condition, that we should view the prospect without undue apprehension. The question of price readjustment in the United States is tied up with our attitude toward Europe's economic recovery. If it is felt that we are all involved to a significant degree in a common economic future, our participation will doubtless be active. As a part of such a policy, new loans to Europe to make possible a continuance of our exports essential to reconstruction would delay the process of price readjustment.

"Withdrawal of the present extensions of credit to support exports to Europe would soon check the present abnormally one-sided trade. This would necessitate our domestic market's absorbing three or four hundred million dollars worth of goods each month which our market has not had to absorb during 1919. With goods thrown back on the domestic market in this volume a relaxation of the strain in our commodity markets would follow. Two possibilities would then be opened. On the one hand, we might have a speedy readjustment of prices and wages and a revival of business activity on a lower level. On the other hand, if efforts were made to resist price reduction by artificial means, we would be exposed to the dangers of a painful period of real business depression.

"When this readjustment comes, the business men of the country will have opportunity for a policy toward labor which will go far in making for industrial peace in the years that follow. To so far as balance-sheets permit it, business men will find it wise to let prices go down first without making too vigorous efforts to reduce wages. The natural course of events will lead to substantial wage reductions in time. However, we cannot expect to see wages reveal as rapidly or as far as prices, because the elimination of unemployment in recent years has left our labor supply relatively short. Even without reduction in wages, labor costs per unit of output will be reduced with the restoration of shop discipline and the cessation of overtime work.

"The great change in prices in the United States has been due, not to a fall in the value of gold, but to a rise in the value of goods. At the present time forces are at work tending to make the value of gold rise rather than fall. High prices and high wages are curtailing gold production, and with diminished production there has come also an increased industrial consumption of gold. At the present time the arts and industries are consuming more gold in the United States than our gold mines are producing. If no other factor were at work, this would mean in the long run a fall in prices."

Foreign quotations on February 10 are as follows:	
Sterling, dollars:	Cable 3 30 1/2
France, cents:	Cable 6 91
Italy, cents:	Cable 5 49
Mark, cents:	Cable 1 15

Eastern Metal Market

New York, February 4.

The markets are all quiet but prices are firm in most cases. The very low levels to which foreign exchange has fallen is the predominating influence.

Copper buying has fallen off but prices remain steady.

Tin values have fluctuated with that of the pound sterling and have declined decidedly.

The lead market is quiet but still strong.

Demand for zinc is light and prices are slightly easier.

Antimony remains strong.

IRON AND STEEL

A serious car shortage is one of the predominating factors confronting the steel industry today. Its seriousness can hardly be overestimated. Inadequate coal and coke supplies have forced the banking of more blast-furnaces and 50,000 tons of finished steel is piled at the leading interest's yards in Chicago waiting for cars, and an Eastern company has stored 30,000 tons of structural steel alone. At least 25% of the foundries in the Cleveland district are shut down partly or wholly because of a lack of fuel.

Many iron and steel producers have withdrawn from the market. In Chicago the leading interest has no shapes, plates, or bars to sell, nor rails or track supplies. Some pig-iron makers will book nothing further for 1920. Pig-iron sales have been very large.

The January pig-iron output, despite adverse railroad conditions, was better than any month since March 1919. The output, according to 'The Iron Age's' monthly report, was 3,015,181 gross tons as compared with 2,633,268 tons in December, both 31-day months. The daily January average was 97,264 tons or 14½% more than in December, which averaged 84,944 tons per day.

The Steel Corporation's advance in wages of 10%, announced a few days ago, has hardly caused a ripple in the steel market as \$1.50 to \$2 more per ton would probably balance the increased output.

COPPER

Demand is reported to have slackened considerably. It is even stated that some inquiries have been withdrawn from the market. Prices continue fairly firm with leading producers and most of the small ones quoting 19.25c., New York, for electrolytic for early delivery, with Lake held at 19.50c. The erratic and low values of exchange have interfered with any foreign business that might be possible and not much buying for foreign consumption is looked for until exchange values are more stable. For second quarter delivery for domestic consumption, values are about 19.50c., New York, for electrolytic and 19.75c. for Lake.

TIN

The market has been almost completely controlled by the value of the pound sterling which has fallen daily to the lowest levels on record. Because of this, spot Straits has also declined each day until yesterday it was quoted at 59c., New York. This is a fall of 3.25c. per pound in the week. The decline in London has not been as heavy. Yesterday spot Straits was quoted at £386 5s. per ton, as compared with £393 a week ago. The market has been very quiet with but little business reported, most of it having been between traders. Consumers are naturally waiting developments. In future shipments, little also has been done, there being little desire by sellers to do business for this position. Quotations for this delivery are about ½ to 1c. above those for spot shipment. Deliveries of tin into consumption were 3910 tons in January, of which 910 tons are credited to Pacific ports. In stock and landing on January 31 there were 3723 tons. Tin afloat is reported as 5030 tons.

LEAD

The amount of lead available seems to be nearly equal to the demand which has been light. The market continues strong with prices firm at 8.75c., New York, and 8.45c., St. Louis, for early delivery. Spot delivery is available at 8.75 to 8.87½c., New York, at which prices some business has been done. Production is reported to be improving.

ZINC

The market has turned quiet and almost stagnant. While the drop in foreign exchange has not had the effect in this market as in some of the others, it has been a factor. This decline has been offset to some extent by progressive advances in the price of zinc in London. Domestic demand here has fallen off some, though it has been fairly good. Consumers, however, are in general inclined to wait developments. Prime Western for early delivery is now quoted at 9c., St. Louis, or 9.35c., New York, and these prices are fairly firm despite general conditions. Foreign sales and demand are a minor matter under the circumstances.

ANTIMONY

Demand is good and the market is strong at 11.25c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

Wholesale lots of virgin metal, 98 to 99% pure, are quoted at 31.50 to 32.50c., New York, for early delivery.

ORES

Tungsten: The market is marking time pending some decision as to a tariff. Inquiry is light and prices are nominal at \$6 to \$15 per unit, depending on the grade. Ferro-tungsten is quoted by one authority at about \$1 per lb. of contained tungsten.

Molybdenum: Quotations are unchanged and nominal at 75c. per lb. of MoS₃ in regular concentrates.

Manganese-Iron Alloys: Ferro-manganese for spot delivery has sold as high as \$185, delivered, and is very scarce. Very little alloy is available for first half, most of the British alloy offered for delivery from April and May on, having been sold at \$145 to \$150, seaboard. About 4000 tons has been sold. American producers are asking \$160, delivered, for second half and it is said some sales have been made.

In 1913, writes H. M. Ridge in 'The Journal of the Society of Chemical Industry', the world's spelter production amounted to 982,000 tons, of which 32% was made in the United States, 28% in Germany, and 20% in Belgium; In Great Britain only 6% was made, although the consumption amounted to 23% of the metal produced in the whole world, while in the whole of the rest of the Empire only 3700 tons was produced. As a consequence an acute shortage of metal was experienced during the War and prices rose phenomenally. Schemes were prepared for increasing the output, but with the whole of the smelting capacity of the United Kingdom in operation only 80,000 to 85,000 tons could now be produced annually. For the ten years before the War the average price of g.o.b. spelter in London was £23 16s.5d. Since then the average prices have been:

1914£23	6	8	1917£52	3	6		
1915	66	13	8	1918	52	4	0
1916	68	18	11	1919	42	5	3

At the present time production is progressing satisfactorily in America, but Belgium is producing only 6500 tons per month, or 39% of the pre-war output, and Germany 3500 tons, or 14%, and Great Britain 2000 tons, or 40%. It is obvious that until conditions improve we are dependent on American supplies.

Company Reports

TOMBOY GOLD MINES CO., LTD.

Report for year ending June 30, 1919.

Property: mine, concentrator, and cyanide plant in Telluride district, Colorado.

Operating Officials: D. A. Herron, general manager; J. S. Peterson, assistant manager.

Financial Statement: bullion and concentrate production for the year, \$864,699; cost, \$781,397; net profit, \$83,302.

Dividends: none in 1919. Total to date, \$4,074,200.

Development: little work done in Argentine group; ore-reserves estimated to be 200,000 tons. Only 1378 ft. of development work in Montana group due to scarcity of labor. The north drift of the Virginus vein was followed 552 ft. Ore-reserves estimated to be 300,000 tons.

Operations: 155,334 tons ore milled; 122,624 tons of tailing cyanidized. Mining cost \$2.21; milling, \$0.67; concentrating, \$0.53; cyaniding, \$0.88; general and other expense, \$0.74.

Production: bullion, \$265,796; concentrate, \$437,713; cyanide bullion and slag, \$161,190.

EL ORO MINING AND RAILWAY COMPANY, LTD.

Report for the year ending June 30, 1919.

Property: mines and railway at El Oro, Mexico.

Operating Officials: A. F. Main, general manager; F. Jenkins, assistant manager.

Financial Statement: the annual report gives 'profit and loss' accounts of years 1916, 1917, and 1918, which show a loss of £19,000, a profit of £95,000, and a profit of £57,000, respectively. The net profit for 1919 was \$391,197. During the year State and Federal taxes amounted to \$299,578. The railway earned \$117,219, net. Balance sheet shows a credit of £229,621 in war and exchequer bonds.

Dividends: dividend No. 28 of 1s. per share was paid on October 31. Total to date: £2,000,000.

Development: developed ore on June 30, 1919, was 333,600 tons as compared with 292,000 tons on June 30, 1918. Working costs were \$6.80 per ton.

Production: ore treated totaled 308,717 tons of an assay value of \$8.79. Bullion produced \$526,697. Net recovery of gold and silver was 90.11%.

SANTA GERTRUDIS COMPANY, LTD.

Report for year ending June 30, 1919.

Property: mine in Pachuca district, Mexico. Also 60-stamp mill and cyanide plant.

Operating Officials: Hugh Rose, general manager; C. A. Lantz, assistant manager; T. C. Baker, mine superintendent.

Financial Statement: profit for the year, £158,408. Brought forward, £1497. Appropriations and dividends, £151,584. Carried forward, £8322.

Dividends: dividends No. 8 and 9 amounting together to £150,000 were distributed.

Development: the estimated ore-reserves on June 30, 1919, were 718,500 tons containing 44,565 oz. of gold and 7,921,000 oz. of silver. Development during the year amounted to 8162 ft. of drifting and cross-cutting.

Production: 381,428 tons of ore was treated from which 24,359 oz. of gold and 4,304,812 oz. of silver were recovered as bullion. Labor conditions were satisfactory. Operating cost is still high on account of cost of supplies and high wages.

CAMP BIRD, LTD.

Report for year ending June 30, 1919.

Property: mine and stamp-mill near Telluride, Colorado. Large holdings of Santa Gertrudis stock.

Operating Officials: Thos. H. Woods, general superintendent; J. B. Glasser, purchasing agent.

Dividends: No. 17 and 18 amounting to £45,473 were paid during the year.

Development: 3212 ft. of development work.

Operations: confined entirely to mine development. Mill did not run during the fiscal year.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

FEATURES OF THE ELECTRICAL EQUIPMENT OF THE ALASKA JUNEAU GOLD MINING COMPANY

By F. Seward Rice

The first unit of the 6000-ton concentrator of the Alaska Juneau Gold Mining Co. was put into operation in June 1917. This plant was built to treat the gold-bearing ore from the Alaska Juneau mine, one mile north-east of Juneau, Alaska. The concentrator-site adjoins the city of Juneau

Fig. 1. Concentrator, Just South of Juneau

on the south-east, and is built on a steep rocky cliff fronting Gastineau channel and nearly opposite the famous mine and milling-plant of the Alaska Treadwell Gold Mining Co. on Douglas island.

Electric-power is generated in a 12,000-kw. steam-turbo generator-plant which was built in 1916. This power is used throughout, for all mining and milling operations. The steam station is tied-in through a bank of 22,000-volt transformers with the distribution system of the Alaska Treadwell Gold Mining Co. This distribution system is fed by both hydro-electric and steam plants and through the arrangement in force all plants of both mining companies are able to interchange power and serve as auxiliary sources of electric energy. Only one-half of the ultimate capacity of the Juneau steam-station was installed at first. This consists of a 6000-kw. horizontal steam generator with corresponding boiler-plant and auxiliaries.

The broken ore in the mine is gathered with Baldwin-Westinghouse storage-battery locomotives of approximately 5½-ton weight equipped with Edison A-10 batteries. From the mine the ore is hauled to the mill, a distance of two miles, in trains handled by Baldwin-Westinghouse trolley locomotives. The railway is also used for handling supplies between the mill and the mine. The double track has a maximum grade of $\frac{1}{2}$ of 1% in favor of the load descending from the mine to the mill, and passes through three tunnels. Between tunnels the road is protected by snow-sheds wher-

ever it is exposed to slides, which were formerly a frequent source of trouble. The ore-trains are made up of cars of 10 tons capacity each. The average train weighs 416 tons loaded and 96 tons empty. The locomotives are articulated tandem-units particularly designed for the service. Each locomotive consists of two 3-ton bar-steel units. Each unit has two motors, the control for all is assembled in a cab on the rear end of the loading-unit. These 18-ton locomotives were built to special dimensions in order to conform to the gauge, which is 30-in., and in order to permit the locomotive passing entirely through the tippie at the mill. The motors are the Westinghouse No. 305 type, which are provided with forced ventilation. The compressors are mounted on the leading unit of the tandem, while the air-storage cylinders are divided so that the cylinder for straight air is on the leading unit while the auxiliary storage-cylinder for automatic air is on the trailing unit. Through this arrangement the leading unit may be disconnected from the trailing unit and used by itself as a switching-locomotive with air-brake equipment. The locomotives are somewhat unique in that considerably more apparatus has been mounted upon them

Fig. 2. Synchronous Motor in Crushing Department

than is usually found in units of this size. Still, it has been so well placed, and so compactly grouped that the whole appearance of the locomotive is good and accessibility of all parts is excellent. The locomotives have been found to be easily handled under exacting service conditions and have shown that they are fully capable of hauling in two 8-hour shifts the full tonnage of ore required to keep the mill running at maximum capacity three shifts per day.

The direct-current power-supply for the railroad is derived from two 300-kw. rotary converters, one situated in the power-house, and one in the Gold creek substation. The latter feeds into the trolley near the portal of Sheep creek tunnel, two-thirds of the distance from the mill to the loading-bins in the mine. Each rotary converter has its individual 300-kw. 6-phase transformer. The one in the power-

house has a primary voltage of 2300, corresponding to the generated voltage, and the other has a primary voltage of 22,000, which is the voltage of the Alaska Treadwell company's transmission system.

The ore from the trains coming from the mine is dumped into the crude-ore receiving-bins at the mill by either of two revolving tipples. These tipples have a capacity of 4 cars each. They are each driven by a 25-hp. 550-volt D.C. motor.

Fig. 3. Ball-Mill Department

It is possible to dump an entire train of 32 cars in a period of 10 minutes. The tipple motors are hand operated by reversing-drum controllers which serve to align the wheels with the track rails whenever the tipple is turned over. It has been found that there is considerable force tending to accelerate the motion of the tipple during the last quarter revolution, due to the fact that the centre of gravity of an empty car is below the axis of the tipple. Consequently in order to bring the tipple rails quickly into alignment with

motors are entirely suitable for such service. The motors have given entirely satisfactory mechanical performance and at the same time provide the additional advantage of improving the power-factor of the electrical distribution-system. The slow speed which can be efficiently obtained with synchronous motors has permitted the elimination of counter-shafting and extra belting, thus permitting a most excellent arrangement of the crushing department from the mill-operator's point of view.

The crushing department is in two sections, each containing two No. 9 gyratories set to crush to 3 in. and a 36 by 48-in. jaw-crusher. Each section is driven from a single shaft to which the crushers are connected by friction-clutch pulleys. Each shaft is directly coupled to a 350-hp., 420-kva., 360-r.p.m., 2200-volt Westinghouse synchronous motor, with direct-connected exciter. The motors are designed with heavy starting-torque and good synchronizing characteristics, so that even in case of the clutches becoming clogged with dust, they will permit starting without undue strain. The starting control for the motors has been simplified to such an extent that the operation of putting them into service is entirely analogous to the starting of an induction motor. The use of direct exciters permits the motor fields to be short-circuited through the exciter-armatures, and the exciter builds up voltage as the synchronous motor comes up to speed.

The grinding department of the concentrator has twelve 8 by 6-ft. ball-mills, each driven from a 225-hp., 435-r.p.m., 2200-volt, type 'CS' motor. Fine grinding is done in twelve 6 by 12-ft. tube-mills, each driven by a 150-hp., 435-r.p.m., 2200-volt, type 'CS' Westinghouse motor. Although it was anticipated that the starting-duty of these motors would be rather severe, squirrel-cage motors were chosen instead of slip-ring motors. Slip-ring motors have been more often used for this class of service in order to obtain adequate starting-torque and to relieve the generating-station of the high peak during starting. In the present instance the peak

Fig. 4. Special 18-Ton Electric Locomotive

the track rails without over-running the centre, it is frequently necessary to plug the motor, and to have a means, such as is provided in the drum controller, of easily reversing it, in the event that the tipple turns past its track-centre.

The coarse-crushing department at the mill is somewhat unusual in that the crushing-machinery is all driven by synchronous motors. This type of motors has not generally been used for this duty, but there is no reason why a properly designed synchronous motor should not be applied to crusher-drives. The success of the Juneau operations has definitely proved that properly constructed synchronous

motors were small in comparison with the capacity of the power-system and adequate torque was ensured by designing the motors for as high a starting-torque as could be secured without sacrifice of efficiency. The slight resultant sacrifice in power-factor was offset by the synchronous installation in the crushing department. Squirrel-cage motors seemed advisable owing to the simplicity of their starting equipment and the elimination of any possibility of trouble from dust, which was anticipated owing to the dry quality of the ore. In order to simplify starting, both the ball-mill and the tube-mill motors are thrown directly on full-line voltage by means of specially

selected circuit-breakers, no starting compensators whatever being used. Each ball-mill and tube-mill has a friction-clutch pulley on its pinion-shaft so that the motor can be started ahead of its load, but in actual practice these clutches are seldom used and the motors have proved fully capable of starting satisfactorily with the mills connected. As the torque of an induction-motor is very nearly proportional to the square of the voltage impressed on its terminals, the maximum possible starting-torque is secured by connecting the motors directly to the 2200-volt circuit as described above. Of course, this high starting-torque is secured at the expense of drawing a large line-current from the power-feeder at the moment of starting. Ordinarily this large current-flow might produce poor voltage regulation on the feeder, and might impose a heavy momentary drag on the prime mover at the generating station. The first source of difficulty is obviated by the use of amply heavy feeder-cables, and in this particular installation the second creates no trouble owing to the comparatively large capacity of the power-supply. The large available power-supply was taken advantage of in this case to secure the maximum simplicity of electrical operation.

Special forms of belt-drive from the motors to the mills were selected owing to the steep gradient of the ground on which the mill is situated. Short vertical centre-drives with counter-weighted idler-pulleys are used and are so arranged that they occupy a minimum amount of horizontal space. This was a desirable feature owing to the economy in limiting the width of the mill section. The pulley of each ball-mill motor is directly beneath the driven pulley on the pinion-shaft of the mill which it drives. The drive on the tube-mills is similar, except that they are so arranged that the motor-pulley is directly above the driven pulley on the mill-pinon-shaft. It will be seen that in the case of the ball-mill motors the shaft reaction due to the belt-pull is vertically upward against the bearing-caps. A careful check of the design of the bearings prior to installation showed that they were amply capable of taking care of this vertical reaction and no trouble due to this feature has been experienced.

The water-supply for the mill and the circulating cooling-water for the plant condensers is pumped from Gastineau channel. The pumping-plant is in a sub-basement of the power-house. The pumps are set 18 ft. below maximum high-tide level in order to equalize the head due to tide-variation, which at its greatest rise amounts to 26 ft. The mill-pumps, of which there are two, have a combined capacity of 6000 gallons per minute, and are driven by 400-hp. direct-connected squirrel-cage type induction-motors. These pumps deliver water to the storage-tanks above the concentrator. Circulating-water is pumped by two centrifugal pumps, each of 12,000 gallons per minute capacity. Two 300-kva., 720-r.p.m., 2200-volt synchronous motors drive these pumps. These motors are designed to carry from 180 to 270 mechanical horse-power with maximum power-factor correction. They are coupled to the pump-shafts through jaw-clutches, which when disconnected permit the use of either motor as a synchronous condenser for power-factor correction. The rheostats in the field-circuits of these motors are controlled either from the motor-starting panels near the pumps in the basement or from the main switch-board in the power-house on the floor above. Instruments and remote-control field-rheostat at the latter position give the switchboard attendant control of the amount of power-factor correction which it is desired to effect.

The design of these synchronous motors differs considerably from those used in the crushing-plant. For the motors in the crushing-plant, as explained above, high-starting torque was desirable. In starting centrifugal pumps the starting-torque is low, but the required running-torque increases as the speed approaches synchronism. Therefore,

the synchronous pump motors were designed with particular regard to obtaining high synchronizing torque. The design employed giving a synchronous-torque of 33% of full-load torque has proved entirely successful. These motors are not provided with direct connected exciters, but obtain their excitation from the exciter circuit in the power-house.

The complete crushing and concentrating-plant, as well as the power-house of the Alaska Juneau Gold Mining Co., were designed by Bradley, Bufl & Labarthe, engineers, of San Francisco. The electrical equipment described above, including all motors, rotary converters, transformers, and switchboard, was supplied by the Westinghouse Electric & Mfg. Co., who designed the locomotives, the synchronous motors, and the motors for the grinding-department along special lines to meet the requirements specified by the plant designers.

COMMERCIAL PARAGRAPHS

W. E. Hardy, F. H. Rice, and H. H. Whitesell, and associates who have been operating the **Boston Belting Corporation** (so far as production and sales are concerned) have purchased and taken over all assets of the corporation which relate to the mechanical rubber goods business.

The **National Tube Co.** has issued Bulletin No. 24, discussing the 'Rise of Steel Pipe'. Showing the growth in the manufacture of steel pipe from practically nothing in 1888 to more than 2,600,000 tons in 1918 and pointing out the advantages of steel as compared with wrought-iron pipe.

'Insuring Full Return on Truck Investments' is the title of a new 81 by 11 four-page descriptive leaflet known as Publication S96, printed by **The Cutler-Hammer Mfg. Co.**, of Milwaukee and New York. This leaflet describes and illustrates the new C-H automatic sectional type of battery-charging equipment for charging battery-driven vehicles, trucks, and locomotives.

The **Wisconsin Bridge & Iron Co.**, with general offices and works at North Milwaukee, has opened an office at 709 Caples building, El Paso, Texas, with E. P. Rankin, Jr., in charge. The company is now engaged in constructing the new Bisbee concentrator for handling ore from the Phelps Dodge mines at Sacramento mountain. Mr. Rankin has been designing and contracting in the South-West for the past ten years.

The **Hardinge Company** is the new corporate name of the **Hardinge Conical Mill Company**, whose main office is at 120 Broadway, New York, with branch offices at Denver, Salt Lake City, Spokane, and London. This alteration in name in no way indicates any change of policy as regards the building and distributing conical mills, but is rather in keeping with the idea of efficiency, and also reflects enlargement in the scope of activities.

'Worthington Condensing Apparatus' is the title of a new booklet issued by the **Worthington Pump & Machinery Corporation**. The first 85 pages are devoted to illustrations and reading matter descriptive of the various types of condensers made by the Worthington company, together with auxiliary apparatus. This is followed by 26 pages of useful information for the benefit of steam users and engineers. It is an attractive publication.

A change in the merchandising policy of the **R. D. Nuttall Co.**, of Pittsburgh, Pennsylvania, has been announced, effective January 1, 1920. Under the new arrangement the Westinghouse Electric & Manufacturing Co.'s salesmen throughout the United States will handle the railway and mine products of the R. D. Nuttall Co. All Nuttall industrial lines and other products, however, will be taken care of through the main Nuttall office at Pittsburgh, Pennsylvania.

Realizing the tremendous possibilities in the Orient for intensive sales development, the **Pioneer Rubber Mills** of San Francisco will send D. D. Tripp, vice-president, on an

extended tour through that territory. Mr. Tripp will leave shortly and will visit Japan, China, French Indo-China, India, Straits Settlement, Java, Manila, Australia, etc. Mr. Tripp is really going in the role of a trained observer, as he will be accompanied by the regular line salesman.

I. F. Baker of the Westinghouse Electric International Co., who has been at the New York office of that company for the past two years, is now on his way to Tokyo, Japan, where he will act as a special representative of the International company. Mr. Baker entered the graduate student course about 1908, later serving in various capacities in the resale and contract sections of the sales department. In 1913 he was transferred to the foreign department which later became the Westinghouse Electric International Co. Mr. Baker has many friends in the Electric as well as in the International company and will carry with him their best wishes for success in his new field.

The Cutler-Hammer Mfg. Co., of Milwaukee, has revised and reprinted two of their standard descriptive booklets. Booklet 'A' describes the C-II motor-operated brakes for alternating current service, made for application similar to the direct current type M magnet brake, such as used for cranes, elevators, mine hoists, and other kinds of conveying and hoisting machinery. Booklet 'S' illustrates and describes the C-II magnetic separator which is used in 35 different industries. The three principal uses may be classified as follows: (1) Cobbing, or removal of stray iron that would injure crushing, grinding, or cutting machinery; (2) recovery of iron for its intrinsic value, as found in refuse sands from foundries; and (3) the purification of products.

The Coast Equipment Co., with offices in the Merchants Exchange building, San Francisco, has been appointed exclusive sales agent for California and Nevada for the following companies: Ridgway Dynamo & Engine Co., manufacturing turbo-generator sets, alternating and direct-current generators, motor-generator sets, steam-engines, and synchronous motors; Pittsburgh Transformer Co., transformers; Atlas Car & Manufacturing Co., electric storage-battery and trolley locomotives, storage-battery flat-cars and industrial cars; Norwalk Iron Works Co., air, oxygen, hydrogen, and carbonic-acid gas compressors, and automatic ammonia compressors; Duncan Electric Manufacturing Co., watt-hour meters. The company has recently opened an office in the San Fernando building at Los Angeles, in charge of Ralph B. Clapp.

Many industrial plants are using Oronite roof paints not only for painting both metal and prepared roofing, but also as a protective coating in all cases where an extra heavy or thick coating is necessary. Other plants are using this paint for repairing old paper roofs that have got into bad condition. In this connection it has given perfect satisfaction when used for patching holes in old roofs. A certain sugar company in California uses Oronite roof paint on pipelines at its plant with excellent results. A copper company in Arizona is using it for protecting fuses in wet holes, and state that it is the best material it has ever found for the purpose, as there has not been a missed shot since its use. Another use of Oronite, and one for which it is excellently suited, is on cuts, abrasions, and wounds of trees. Many municipalities are employing it for this purpose.

The Booth Electric Furnace Co. has opened the following district offices in connection with the sale of electric furnaces for melting steel, iron, and non-ferrous metals: For New York and New England, Edward B. Stott & Co., Flatiron Bldg., New York City, with E. F. Tweedy, secretary of the company, directly in charge; for eastern Pennsylvania, New Jersey, Maryland, Delaware, and southern Atlantic Coast States, Northern Engineering Co., 308 Chestnut St., Philadelphia, with F. W. Doran in charge; for north-eastern Ohio, western Pennsylvania, and western New York State, C.

L. Foster, formerly sales manager of the Electric Furnace Co., of Alliance, Ohio, with offices at 879 The Arcade, Cleveland, Ohio. In connection with these district offices a complete staff of engineers and metallurgists will be maintained so that the needs of customers can be promptly met and adequately taken care of.

The Barrett Company, well-known producers of flotation reagents, has announced the establishment of a flotation-oil department. The increased use of coal-tar products in this important branch of metallurgy has necessitated this step. It is understood that the function of this new department will be to carry on a conservative advertising campaign in favor of a more general use of coal-tar products in flotation, and to bring to the assistance of the mining companies its knowledge of coal-tar technique with the idea of assisting them to choose their flotation reagents more intelligently. The new work has been put in charge of F. G. Moses, a flotation engineer of broad experience. Mr. Moses recently severed his connection with the Salt Lake City station of the U. S. Bureau of Mines to take up this work for The Barrett Company. Before entering the employ of the Government he was engaged as a flotation engineer on the staff of J. M. Callow, during which time he investigated ores and operated flotation plants in various sections of the country. He has a wide understanding of the problems encountered by the flotation operators. Mr. Moses is also known as the author of several timely articles on flotation which have appeared in the technical press.

Fairbanks, Morse & Co. will start the erection in Beloit next year of the most modern foundry in the world. It will equal in size and output any foundry on the globe. This great structure, when completed, will be 900 ft. long, 550 ft. wide, and will contain 495,000 sq. ft. of floor space. This structure, including storage of flasks, iron, sand, etc., which will also be under the roof, will cover eleven acres of ground. It will be located directly to the north of the present powerhouse, bordering the River road. The plant when completed will have an ultimate capacity of 350 to 400 tons of gray iron daily. This big foundry will eventually employ 1500 additional men; and 1500 more men will be required in other departments of the factory to meet the increased production that will result. This means an addition of 3000 workmen for the great plant, an increase of 75% in its industrial army. Fairbanks, Morse & Co. will then employ 7000 men. Plans and specifications for the big foundry are rapidly nearing completion. Raw material for its construction will be placed on the ground this winter and work will be begun as soon as the frost is out of the ground. The officials of the company decline to give out figures as to the cost, but it is hinted that at least \$1,500,000 will be expended. Many months have been spent in planning this enterprise, with the result that every protection for the safety and health of the employees, every modern scientific foundry device, every improvement in the casting of gray iron will be incorporated in the Beloit plant.

Electric cranes will carry the raw materials to and from the big cupolas. Electric grab-buckets will unload the molding and core sand and coke. Electric magnets will grip the raw pig-iron and remove it from the cars. Electric cranes and conveyors will carry all molten metal from the cupolas to every mold, whether for giant castings of 10,000 lb. or for tiny ones of a few ounces. When the eleven-acre building is completed it will be the most up-to-the-minute foundry in the world not only in efficient handling of materials but in provisions for ideal working conditions. In order to ensure a maximum of comfort for the workmen the plant will contain a complete ventilation system that will change the air in the vast structure frequently; individual lockers for all workers; a complete system of hot and cold shower baths for the entire force; and a modern cafeteria where the men can secure hot meals.

FROM Houghton comes the following telegram: "At a meeting of student body Michigan College of Mines Mr. Herbert Hoover was unanimously endorsed and urged to run for Presidency of the United States of America regardless of party, at present the College assays 85% ex-service men and of voting age. J. M. Flanagan, Secretary, Student Body." We always thought that the Michigan College of Mines was a first-rate institution, and now we know it.

DETAILS of Mr. Hoover's life are being given by his friends, as would be expected. Some of them are erroneous. For example, Dr. Jordan, at Berkeley, talked a good deal of nonsense about a gold mine in Burma out of which Mr. Hoover had made his fortune. The Baldwin mine, of the Burma Mines Corporation, is not a gold mine, as most of our readers know; it yields silver, lead, and zinc. Mr. Hoover sold his stock in it three years ago, at a moderate price. It was not the source of any large part of his fortune, which has been the fruit of 25 years of highly successful professional work, supplemented by participation in scores of honorable mining enterprises. On page 286 we publish a statement by Mr. Hoover. It has a touch of humor that lightens these days of gloom and rancor.

COAL operations is to be the subject of an inquiry initiated by Mr. Herbert Hoover, in his capacity as president-elect of the American Institute of Mining Engineers, which organization will hold its annual meeting at New York on February 17. The engineers will have a conference, to discuss the stabilization of the coal industry, that is, to ascertain how much the intermittent operation of the mines and the consequent irregular employment of the miners are necessary. The Director of the U. S. Bureau of Mines, Mr. Van. H. Manning, and the Director of the U. S. Geological Survey, Mr. George Otis Smith, will lead the discussion. They will be followed by Messrs. H. H. Stoeck, S. L. Yerkes, and Eugene McAniff. A timely and useful exchange of ideas is assured. At this meeting Mr. Hoover will preside, as President. This is a good omen, is it not?

CANADIAN GEOLOGISTS are like American geologists in expecting their government to give them a living wage. We referred recently to the loss suffered by the personnel of the U. S. Geological Survey on account

of resignations caused by the inadequacy of the salary paid to members of the staff. The same blight has fallen upon the Canadian Geological Survey. Out of a field staff of 25, no less than 13 have resigned since last October. As an example of the lack of appreciation for scientific service shown by the Government, and back of it, of course, the Parliament of the Dominion, we may instance a graduate of McGill university who was receiving \$2100 per annum after having been on the Survey for ten years. He was offered, and accepted, \$5600 per annum from Pearson & Son. All the younger men are leaving the Survey, and we do not blame them. One may love the rocks, but one cannot live on them.

SINCE the third article on the Bunker Hill enterprise appeared, in our issue of January 24, we have received a letter from Mr. Walter C. Brower, of Spokane, stating that he was a friend of Noah Kellogg, and that Kellogg, three years before his death, told him the true tale of the grubstake. Mr. Brower has sent us a detailed account, not for publication, of the story as told to him by Kellogg. From this it appears that our surmise as to the main facts was correct. Kellogg's confession may be summarized as follows: He had failed to find any outcrop of gold ore, he had found only the combs of hungry-looking ironstone so common in the quartzite hills overlooking the south fork of the Coeur d'Alene river, and he was about to return disappointed to Murray from his last camp at the mouth of Milo creek. His donkey had strayed up the gulch and to the adjacent hillside. "When Kellogg got near to him," says Mr. Brower, "he saw where he had stepped into a gopher-hole and kicked out a quantity of loose dirt, among which were pieces of shiny white metal. Kellogg picked up as much as a pound of what proved to be galena, and when he looked about him he found the burro standing near a great outcrop of discolored capstone which he could plainly see extending across the creek, and showing on the opposite hillside. The great Bunker Hill dike was discovered." Some of this is Kellogg and some of it, inevitably, is Brower. It is possible that a few specks of unoxidized galena might be kicked out of a hole made by a gopher, but it is unlikely; it is more probable that the vagrant burro found a patch of bunch-grass close to the outcrop and that Kellogg, in looking for his companion, saw the comb of rock and chipped it at a place where unoxidized galena was not

far below the outer cover of oxidized ore. In any event, Kellogg found some galena and located the lode forthwith. So he told Mr. Brower. Then he returned to Murray, where he went straight to O'Rourke's cabin and showed him the "shiny mineral", which O'Rourke recognized as galena, probably silver-bearing. There and then they 'put up a job' on Cooper and Peck, who had grubstaked Kellogg. It was agreed that only the pieces of ironstone should be shown to the grubstakers, who had no use for such poor-looking stuff, thereby giving Kellogg a chance to terminate his agreement with them. O'Rourke arranged to go with Kellogg to the scene of the discovery, where Kellogg's first location notice was torn down and thrown aside—to be found later by Peck—while a new notice with their joint names was posted. Mr. Brower says that Kellogg also stated that 'Dutch Jake' eavesdropped into the secret, by listening outside O'Rourke's cabin, and that was how 'Dutch Jake' and Sullivan happened on the scene at the critical moment. We give this version for what it is worth; it is interesting as being a confession, through a friend, of Kellogg's wrongdoing; it is in accord with the facts as disclosed at the trial, and it harmonizes with the inferences that were made in our article on the discovery of the Bunker Hill lode; but it is a sordid tale.

A BILL for the compulsory adoption of the metric system of weights and measures has been introduced in the Senate. As has happened before, the proposal is eliciting vigorous protest. For example, we are informed by one of the opponents of the bill, whose views doubtless reflect those held by other executives in an important branch of manufacturing, that "if the bill is enacted, industry in this country will suffer losses of billions of dollars, and will be thrown into a state of chaos that would result in practical paralysis". Such talk is wild. It is a question largely of shop practice. The change, if made, would doubtless be attended by some confusion, considerable duplication of work, and numerous readjustments, all of which involve an increase in the cost of some manufactures. Changes in gauges, screws, and threads, as also in tools, equipment, and design, would ultimately be needed, but it is hardly true that much of the existing machinery would have to be scrapped. If, by legislative fiat, the inch and the pound and their fellow units were stricken from existence, a serious situation would be conceivable; but the proposed act does not contemplate any such drastic procedure. The metric system was introduced in France in 1793 and more than 40 years elapsed before it was finally established, while in Germany a comparatively short period, from 1868 to 1872, sufficed for the necessary readjustment. A commission in Great Britain is at present formulating a report that is expected to make recommendations favoring a change. Reasonable opponents of the adoption of the metric plan concede that if it had been introduced 50 years ago, it would be superior to the present use of our archaic units. The obvious advantages are so many that no intelligent person attempts to base his argument against the decimal system

on the comparative merits of the two plans. Simplicity, standardization, and economy; these are the arguments in favor of the metric system. The partisan whom we quoted asserts that "if the metric system possessed any merit, it would have been put into use in this country years ago, not by force of law, but by expedience. The very fact that the people of the United States have declined to avail themselves of its principles and abandon the system to which they are accustomed, should justify the denial of the passage of the law to enforce its adoption." A fairer statement would be that the metric system, although based on common sense and scientific principle, is an innovation so disturbing to existing custom that it must not be adopted hurriedly, but that it will be accepted eventually. The transitional period will entail some expense in effort and money; but it is probable that even before the new system is entirely established, the saving accruing each year will more than compensate for such additional outlay, and the resulting benefits will increase constantly. There are features in the present economic situation that render it inadvisable to make the change at this particular time; it were better for the opponents of the metric system to point out such facts than try to hoodwink the public with technical falsities and fluent nonsense.

A Medal for Mr. Sulman

We have been notified officially that Mr. H. L. Sulman has been awarded the gold medal of the Institution of Mining and Metallurgy, London, "in recognition of his contributions to metallurgical science with special reference to his work in the development of flotation and its application to the recovery of minerals". The Secretary adds: "The gold medal awarded to Mr. Sulman is the highest distinction in the power of the Institution to confer." There is a note of challenge in this last statement, and we accept it as such. In the first place we congratulate Mr. Sulman, whom we know quite well, on receiving an award that is indeed a great honor, for the gold medal of the Institution is not carelessly bestowed. Next we say deliberately that the news of this award will be received with regret by members of the mining profession in the United States. We speak for them in saying that while it is true that Mr. Sulman has made a highly meritorious contribution to metallurgical science, he has been closely associated with a company whose policy has been to retard metallurgical progress and stifle technical discussion of the flotation process. A few days ago we received a letter from one of the most distinguished of British engineers, in which he protested against the injustice of our criticism of Mr. Sulman's important paper on flotation, recently published by the Institution. We had objected, as our readers are aware, to the complete absence of reference to the numerous writings on the subject printed in the many years during which Mr. Sulman, for commercial reasons, was silent. Mr. Sulman's paper was written, in large part, from five to ten years ago; it contains much material that others

have published in the interval; notably the American Institute of Mining Engineers, as well as the technical press of the United States; he withheld information of great value to the profession until most of it had ceased to have a timely usefulness; his persistent silence during a decade or more can be imputed only to sinister reasons, for it is not to be supposed that the truth about the principles of the process would jeopardize any advantages to which his associates were justly entitled. His company induced many engineers to sign contracts on the promise of full assistance in the working of the flotation process, yet he and the other metallurgists of the Minerals Separation company withheld such knowledge as they possessed and even attempted to prevent others from publishing the information helpful to the successful application of the process. If flotation was developed successfully on a large scale in the United States, the profession in this country owes no thanks, but the contrary, to Mr. Sulman, who in our deliberate opinion, for reasons given more than once, was not the inventor, or co-inventor, of the froth-agitation process. We objected to the praise offered publicly, at the close of Mr. Sulman's paper, to Mr. John Ballot, the chairman of the Minerals Separation company and the man chiefly responsible for a policy that had aroused the keenest resentment in the United States, and elsewhere. The friend in London who objected to our editorial thought we were unjust because Mr. Sulman is not a director of Minerals Separation, but only consulting metallurgist, with his partner Mr. Picard. Now, to be unjust is as deplorable as to be just is admirable. We try to be just. We assumed—and we were warranted in assuming—that Mr. Sulman approved and abetted Mr. Ballot's policy. Mr. Ballot is not a member of the profession. The fact that Mr. Sulman should go out of his way to express admiration for Mr. Ballot's performance was proof of his approbation. Although Mr. Sulman is not a director of Minerals Separation, preferring, most properly, to be retained in his capacity as technician, there is ample reason for believing that he is a large shareholder and a considerable factor in shaping the policy of Minerals Separation. If Mr. Sulman has ever dissociated himself from the policy pursued by Minerals Separation, we are not aware of it. Next, we venture to recall the fact that the gentlemen in London have not been subjected to the exactions and impositions of Minerals Separation as we have in the United States. At Broken Hill, the only mining district under the British flag where flotation is used on a scale at all comparable with its application in this country, the Minerals Separation process has had to compete with the De Bavay, Bradford, and other methods, so that the Broken Hill companies have not been victimized as otherwise they might have been. The scope of flotation in the United States is so vastly bigger than in Australia, or in any other country, as to make the actions of Minerals Separation a real issue, and a most compelling one. Most of the members of the Institution in London can afford to look at the matter in a complacent way. In contrast, we refer the Secretary of the

Institution to the resolution on the subject passed by the American Mining Congress at St. Louis last September. He will find it in our issue of December 13. It makes all the difference whose ox is gored. As Kipling has said:

"The toad beneath the harrow knows
Each quivering tooth-point where it goes;
The butterfly beside the road
Preaches contentment to that toad."

The Railroads

Railroad property constitutes the largest single item of wealth in the United States and the efficient operation of the railroads is a basic factor in promoting the prosperity of our national industry. The price of every commodity is influenced by the cost of transportation, and the welfare of every branch of industry is more or less dependent upon a cheap and at the same time punctual system of distribution. Therefore the management of the railroads is a matter of concern to every citizen, and it is to his interest that the adjustment scheduled for March 1 should be carried out with the utmost fairness and sagacity. We have read carefully the statement issued to "the editors of the newspapers of the United States" by Mr. Walker D. Hines, the Director General of Railroads. During recent unpleasant years we have thought of Mr. Hines chiefly as the person to whom we were bidden to address our complaints of poor service or bad accommodation on the railroads over which we have traveled, and at this moment we marvel at our self-restraint in having declined to avail ourselves of the opportunity to write to him plaintively. However, this has not been allowed to provoke undue prejudice, so we have read his statement carefully, even sympathetically. He discusses first the alleged excessive costs of railroad operation by his administration. These, he asserts, are not so excessive as they seem, for the operating costs of the U. S. Steel Corporation, for example, were 151% more in 1918 than in 1914, whereas those of the Railroad Administration in 1919 were only 102% more than in 1914. Next he states that the Steel Corporation increased its finished tonnage 55% in the four years cited, so that its increased cost per ton was 61%, whereas the railroads increased their service by 26%, so that the increased cost per unit of service was 60% during the five years. As to increase of wages, Mr. Hines quotes the head of the Steel Corporation as saying that the direct labor cost per ton of its products in March 1919 was \$34.61, as compared with \$15.13 in 1913, an increase of 119%. The average pay per hour to labor in the steel industry increased 121% in the six years quoted. On the other hand, the average increase in the pay per hour for all railroad employees increased only 106% during the same period. The increase in wages to railroad employees was, says Mr. Hines, long overdue; the Government could not escape the policy of reasonably uniform treatment; yet the average increase per hour to railroad employees as a whole has been no more than was responsive to the conditions that have forced similar increases

in all industrial enterprises. The increase in the number of employees is due chiefly to the adoption of the 8-hour shift. Between 1917 and 1919 there was an increase of 9.7% in the number of employees and a decrease of 5.9% in the number of hours of work. In 1917 the employees averaged 261.4 hours per month; in 1919, they averaged 218.5 hours per month, that is, 7.1 hours per day as against 8.7 two years previously. It is to be noted that this increase in the number of employees on account of the 8-hour shift does not involve a direct increase in the payroll, because generally the pay is based not upon the number of employees but upon the number of hours worked. Prior to Federal control the train and engine men were working under the Adamson Act, enforcing an 8-hour shift for them, but the other railroad employees were still working longer hours. Another unfavorable factor has been the loss of experienced employees during the War, and since, together with a spirit of unrest that has made men less attentive to their work. These factors have militated against an economical railroad administration. The total deficit on Class I railroads during 22 months of Federal control has been \$480,200,000. Mr. Hines asserts that if the rate increases had been effective at the very beginning of 1918, there would have been no such deficit; he says that it was not practicable for the Railroad Administration to start a general increase in passenger rates until June 10, 1918, and in freight rates until June 25, 1918. He asserts emphatically that "if these increases could have been made effective at the very beginning of Federal control there would have been no deficit whatever from railroad operations up to and including the end of October 1919". After that came the coal strike, which, of course, interrupted railroad traffic to such an extent as to render further comparisons impracticable. The large deficits in November and December, he debits, not unreasonably, to the coal strike. By way of explaining the failure, or the abstention, on the part of the Railroad Administration to increase rates during 1919, Mr. Hines says that, although a small increase in rates was needed to make the railroads self-sustaining, it was thought inopportune to make any change in face of the abnormal conditions arising from the slump in freight business after the Armistice and the subsequent incidence of the coal strike. He adds: "Of course, with a return to private control, consideration immediately thereafter of rates to sustain the credit of the railroad companies is inevitable." Evidently he is in such a hurry to pass the buck that he tangles his phraseology. This is the one weak spot in his apologia. He saves his conscience, or his sense of humor, by saying: "This deficit, therefore, is really due to this conservatism of the administration in deferring a rate increase until it could be reasonably sure as to the basis upon which it ought to be computed." He says that the condition of railroad property is fairly good, although the old equipment has suffered two years of additional wear without being offset by the purchase of as much new equipment as would have been purchased but for the obstacles created by the War. Let us leave Mr. Hines

here; he has done his best to make a good case, and he has told us several things that we ought to remember. It must be admitted that this experiment in Government control was made under untoward conditions. In the first place, the Government had refused to allow the railroad companies to make the rate increases that, later, when it took the job in hand, were found so necessary. Next, of course, the War spoiled the fairness of the experiment, by imposing a set of abnormal conditions. Again, we believe that the common objection to Government control, with the unpleasant changes and restrictions enforced during the War, prejudiced the public against the Railroad Administration; indeed, we think that in our own journeyings we detected a spirit of sabotage on the part of sundry railroad officials who wanted to render the Government control unpopular, as compared with corporate ownership, by giving bad service. Certainly we were subjected to annoyances and breaches of good faith, in the matter of dining-car amenities, sleeping accommodations, and so forth, that would have injured the reputation of any competitive railroad. That is why we are inclined to welcome the return of the roads to the corporations. Shippers will face a rate increase cheerfully if it ensures efficient operation of the railroads. Punctuality is the essence of transportation; promptitude is the very life of commerce. There is a quarter of a million miles of railroad in the United States; the investment may have to be doubled within the next half-century; the 20 billions of capital invested in railroads may have to be increased to 40 or 50 billions. How is confidence to be restored in railroad securities? Apparently it can be done only by making the Government in some way responsible for an adequate return on railroad investments. Congress appears willing to allow the Government to guarantee a return of 5½% on the value of the railroad properties as determined by the Interstate Commerce Commission. The outstanding capitalization and bonded indebtedness of all the roads amount to 19 billion dollars, and 5½% on this sum would entail annual payments of \$1,045,000,000. Half of any surplus will go for betterment of the weaker lines. The guaranteed return to the roads under Government control has been \$900,000,000 per annum. The railway field has ceased to be one for speculative ventures; the people of this country will no longer tolerate the making of big fortunes out of public utilities; they will be glad to see railroad securities placed in the hands of the proposed Interstate Trade Commission, thereby preventing the recurrence of such misdeeds as are associated with the names of the Chicago & Alton and Rock Island railroads. The legislation now pending in the form of the Cummins and Esch bills should create the machinery for the changes necessary to facilitate the resumption of operation by the railroad companies. Government control has been a failure. It is a pity the experiment had to be tried under such unsatisfactory conditions, but most of us will be glad when the experiment comes to an end and some measure of competition is brought into play as a means of stimulating a better service.

DISCUSSION

Chloridizing Processes

Herbert Hoover

The Editor:

Sir.—In his article on this subject, published in your issue of January 17, Mr. Laying states that "the importance of rapid heating is apparently not recognized by Mr. Croasdale, who, after having failed with 25 ft. furnaces, now proposes furnaces of the regular cement-kiln type from 75 to 100 ft. long".

I desire to call Mr. Laying's attention to my paper on the 'Volatilization of Metals as Chlorides' where my original experiments on time variation showed that the maximum commercial volatilization was reached in 30 to 40 minutes after the cold ore was charged into the furnace; also to a subsequent discussion² of this subject where I state: "In this operation there must be at least sufficient temperature to produce chemical action and to make the operation commercial it must be done quickly." This point is again emphasized in a later discussion³ and indirectly, in my reply to Mr. Howe,⁴ when discussing the advantages of a rotary furnace in securing a rapid oxidation and consequently a rapid volatilization of the metals by the continuous rolling or rabbling of the ore.

Where the time of roasting was prolonged to several hours in my original experiments, it was due to the use of a mechanically rabbled reverberatory furnace of the Brown type, which was very popular at that time for roasting ore. We soon found that the ore was exposed to the air too slowly for successful volatilization in this type of furnace, so we turned to the cylindrical type which I think has been found to be the most satisfactory by subsequent investigators.

Our 25-ft. furnace was not a failure so far as the actual volatilization was concerned, but when it was charged to capacity with cold ore it was not long enough to give the ore more than five or ten minutes roast at the volatilization temperature. When fed with a small stream of ore, so that the ore was heated to the proper temperature soon after entering the furnace and had nearly the full length of the furnace, or, in other words, 20 to 30 minutes exposure to the volatilization temperature, the results were all that could be desired.

It is evident that another important feature of this interesting process has been re-discovered and amplified.

Denver, January 22.

STUART CROASDALE.

The Editor:

Sir.—To your three consecutive editorials favoring Hoover for the presidency—and to all other editorials and all other expressed opinions of similar purport—Amen.

The grave conditions confronting our nation require that the next President shall be a man of the highest executive ability, broad experience, and broad vision, a genius for organization, and that he shall have the confidence of the masses of the people. Those conditions need not be reviewed here. The more carefully we may have followed developments in our own country and throughout the world, the more seriously thoughtful we are for the future.

In both political parties are men mentioned for the presidency who in normal times might make acceptable presidents. But the times are not normal; conditions are fraught with real danger for the future; and to the thoughtful not one of the exponents of party politics measures up to the high standard required. Mr. Hoover does. The press quotes him as saying in New York on February 9 that he is not a candidate, and as refusing to pledge his vote to either party "blindfolded". Good! This clears the atmosphere and makes him still more desirable to those of us who agree with you, Sir, that the "country is sick of petty politics", and who want the national 'pie-counter' turned into an efficiency department.

What are we going to do about it? Engineers have been criticized for not taking a more active interest in political affairs—and the criticism is justified. We have been negligent of our duties. Now it looks very much as though the right opportunity to do something thoroughly worth-while is at hand. 'Let's go!'

Two months ago the suggestion of Hoover for President looked like an ideal—something to work toward, but not obtainable. Now it is different: for during the past six weeks the spontaneous spread of the Hoover-for-President-on-any-ticket sentiment, among all sorts of people, of all political faiths, and in all parts of the nation, has been amazing. This sentiment is bi-partisan, rather than non-partisan, and what it needs now is a definite nucleus around which it may crystallize. Here is the chance for the engineers; for it is appropriate that engineers should form this necessary nucleus. The Joint Council of Engineers of San Francisco did well in its resolutions of January 13 endorsing Mr. Hoover. If the Engineers Club was represented, the writer is pleased to have been

¹E. & M. J., August 29, 1903.

²E. & M. J., September 19, 1903.

³M. & S. P., August 9, 1919.

⁴'Mining Magazine', March 1914.

included. I suggest that the Joint Council go further: that it promptly call a meeting, draw up a brief pledge and by-laws and proceed to take signatures. To start the discussion of details, I would suggest that the by-laws show very plainly that there is not the slightest intention to confine the movement to engineers; avoid the names of political parties and also avoid a distinct non-partisan pledge; make it a Hoover-for-President-on-any-ticket movement. Let the pledge and by-laws be printed on slips suitable for pasting on sheets for signatures, with addresses. Submit them to the engineering bodies throughout the United States, and to everybody else who will circulate them. Let each interested engineer appoint himself a committee of one to get busy; call a local meeting among his friends and neighbors, and stir up others to do likewise. No remuneration for circulating pledges should be accepted for the present.

The idea behind this form of movement is this: it is obvious that the public is in a highly receptive mood, and if started *now*, this movement will attain huge proportions. The time to start a political movement is largely a matter of psychology, for feeling and sentiment influence far more voters than does the most logical reasoning.

With several million voters declared for Hoover-on-any-ticket (and just watch the women join us!), we will serve notice impartially on both political parties that we want Hoover nominated; that we have not the slightest objection to his nomination by both parties, but that if he is not nominated by either party, we shall organize our membership into state, county, and precinct divisions, and proceed to elect Mr. Hoover independently. But we hope that the latter move will not be necessary. Sounds like an 'air castle'? Yes, it does. But let anyone who doubts, take about two days and mention the matter to everyone he meets.

If this movement is delayed there will soon spring up both Democratic and Republican Hoover clubs, which will lead to the same old party schisms and ill-feeling, and consequent lost motion. On the other hand, if a distinct non-partisan independent movement is started (as seemed to be suggested in the resolutions of the Joint Council of Engineers), it will not be open to the serious objection which exists to any third party (and which Mr. Hoover is quoted as disapproving), and it would not have injected into it a lot of jarring issues foreign to the main issue.

J. NELSON NEVINS.

Pasadena, February 12.

Public Service and Private Practice

The Editor:

Sir: Your editorial on this subject in your issue of January 17 omits direct mention of "the root of all evil", which, I believe, is at the bottom of the matter under discussion.

Unfortunately, as is too often the case, the ethics and economics of the question clash. There is at present a decided demand in technical schools for instructors with

a wide practical experience, but the salaries offered are generally far below those commanded by men of ability in the lines that they are expected to teach. I believe in the great majority of cases it is the impossibility of offering adequate compensation that leads the governing bodies of the schools to allow faculty members to engage in private practice. The question resolves itself into whether it is better to have as instructors men who are content with the salaries offered, or men with wider experience who are allowed by their private enterprise to augment their incomes to an amount approximating that obtained in strictly commercial pursuits.

The regrettable examples that you cite of professors as 'experts' are too familiar. Is not this condition in most cases due to the inability of the public to disassociate a man's private acts from his public office, and the playing up of his title by a lawyer, rather than any desire on the part of the individual for such notoriety?

Your statement that "teaching gradually unfits a man for commercial work" is the common belief. We have also to consider the attitude of the student, that any subject is more readily and firmly fixed in his mind when instruction is given by a professor who is personally familiar with and who is keeping up on the commercial application of the course of study. Setting aside the question of income, how may a professor keep himself fit for commercial work and satisfy the student body unless by accepting such private practice as does not interfere with his school duties? And what, other than the commercial one, is the object of attendance of the average student of our technical schools?

LESTER S. GRANT.

Golden, Colorado, January 21.

NICKEL MINERALS are known to occur at several localities in Alaska, but none of the deposits have yet been worked. One group of these deposits is described in a recent publication of the U. S. Geological Survey, Bulletin 712-C. They lie 12 miles east of Spirit mountain, in a high range east of Copper river and south of Chitina river, on Canyon creek. Chitina, the nearest town, is about 21 miles away. The country rock is schist cut by intrusive basic igneous rocks. The chief nickel deposit appears to be connected in origin with the basic igneous rock. The orebody is cut by a fault and has not been developed by underground or surface workings, so that its extent is not known. The ore minerals are sulphides which have been altered by weathering. An analysis of the nickel-bearing sulphide was made, but owing to the presence of impurities a formula for the mineral could not be obtained. The other sulphides are pyrrhotite and chalcopyrite. A selected specimen of this sulphide ore analyzed in the Survey laboratory, contained 7.23% nickel.

SOME TUNGSTEN is obtained by placer mining, especially in foreign countries. Most of the domestic production is obtained from lode deposits. In new districts the ore may often be picked up on the surface of the ground or gouged out from shallow open workings.

The Bunker Hill Enterprise V

The Geology and Mineralogy of the Lode

By T. A. RICKARD

The Bunker Hill lode traverses rocks that have been much disturbed and faulted; it has itself been dislocated by later faults. The prevailing formation is quartzite, forming part of the Belt group of the Algonkian system, which is of pre-Cambrian age. No younger sedimentary rocks survive in this locality and no direct connection between the mineralization and igneous rocks has been observed, although the regional metamorphism is supposed to be related to underlying granitic intrusives. Several dikes cross the Bunker Hill workings, but they appear to have no influence on the ore deposition, which is closely connected with the structural conditions created by intense faulting. It will be interesting to trace the growth of knowledge concerning the mining geology by quoting successive writers on the subject.

J. R. Finlay, writing on 'The Mining Industry of the Coeur d'Alenes, Idaho' in 1902, says: "All the ores of the region come from typical fissure-veins, in which argentiferous galena is associated with large quantities of siderite. The fissures occupy fault-planes, on which the amount of movement is indeterminate, but probably, in some cases, considerable. The fissure is usually well marked by a streak of gouge, between walls which are slickensided and often beautifully polished. As a general rule, only one principal plane of fissuring can be found in each vein. This is very apt to occur near the middle of the vein, but often forms one wall of the lode. Two defined walls, marked by planes of movement, are extremely uncommon."

Speaking more specifically of the Bunker Hill lode, he says: "This remarkable fissure differs notably from the other veins of the Coeur d'Alenes. It seems to be the sole source of the ore in the Wardner district. For 6000 ft. from the eastern end of the workings of the Bunker Hill & Sullivan to the Viola claim of the Empire State & Idaho, the workings are continuous. From the Viola north-westward to the Crown Point the continuity of the fissure is not so clearly established, but all the ore that has been found follows the same extended line, and the workings on the Silver King and Crown Point display a fissure with the same dip, strike, and general characteristics as in the Bunker Hill."

He describes the country-rock as fine-grained quartzite dipping S 60° to 70°, striking N 70° W, and marked by folds that probably are subsidiary to "the grand fold of the neighborhood". He proceeds: "The fissure strikes N 30° W and dips 40° SW, thus cutting the stratification at a considerable angle, both on the dip and strike—a

fact which is considered to have a great influence on the deposition and arrangement of the ores. It is a remarkable fact that all the mineralization has taken place on the hanging-wall side of the fissure, which therefore forms the foot-wall of the lode. A characteristic white 'gouge' of thoroughly crushed and altered rock lies upon the unchanged country quartzite of the foot-wall. Lying upon this white gouge is a strongly mineralized zone, which begins with a streak of bluish or black gouge containing galena, always very fine-grained. The lamination of the rocks parallel to the fissure-plane is strongly marked for only a moderate distance (from 5 to 50 ft.) from it; but within this zone of parallel lamination the minerals, valuable or otherwise, are invariably fine-grained. The lamination in this foot-wall zone has reduced the rock to the condition of gouge material only for a foot or two next the foot-wall.

"Passing outward from the fissure, we find the mineralization extending far into the hanging wall, which has undergone much fracturing. For from 100 to 300 ft. from the fissure, the joints and seams in the quartzite are apt to be filled with galena, with subsidiary quartz and iron carbonate. Further from the foot-wall, the quartz, siderite, and pyrite predominate, to the final exclusion of the galena. These minerals give the rocks toward the hanging wall a silicified appearance; and in the outer zone of mineralization they make the rock much harder than the country-rock of the hanging wall or the vein itself, nearer the foot-wall, and sometimes the lode forms great bluffs. For this reason, the prominent outcrops represent this portion of it.

"The quartz, siderite, and pyrite in their turn diminish in amount until at, usually, not more than 400 ft. from the foot-wall, all mineralization has disappeared, and the country quartzite of the hanging wall resumes the appearance of the foot-wall quartzite.

"The workable orebodies in the Bunker Hill lode are simply those portions which contain enough galena to pay for working. Ordinarily, such bodies lie partly in the laminated zone next to the foot-wall or fissure, and partly in the fractured rock in immediate contact with this zone, on the hanging wall. In almost every case, orebodies appearing in some places to be at a considerable distance from the foot-wall have been found, when followed up, to connect with it. There are, however, three conspicuous orebodies, the 'workable' connection of which with the foot-wall has never been established. Two of these (the Curtis-Hatton body in the Bunker Hill, and the hanging-wall stopes in the Last Chance claim) seem

to follow channels made in some way by the fracturing of the hanging wall in a course essentially parallel to the foot-wall, but at some distance from it; and the third, the Sierra Nevada deposit, is a unique occurrence, which merits a more extended description.

"As a general fact, however, it may be declared that the main foot-wall fissure was the source of all the mineral deposition along the lode; that the ore-bearing solutions have enriched portions of the hanging-wall country wherever a favorable channel existed; and that these channels may have been cross-fractures or local branch fissures, regions of extensive crevice-openings due to jointing, or openings along the bedding-planes of the rocks."

I append the sketch of the Bunker Hill lode that accompanies this description by Mr. Finlay. It is a clear description and provides a reasonable explanation of the lode-structure, in the light of the information then available; but it will not stand the test imposed by the later development of the mine and the more detailed study of the local geology.

Next we come to the more elaborate study made by F. L. Ransome and F. C. Calkins for the U. S. Geological Survey in 1903 and 1904 as embodied in the report² published in 1908. These geologists estimated the thickness of the Algonkian rocks in the Coeur d'Alene at 17,200 ft., of which the Burke formation is 2000 ft., the Revett quartzite 1200 ft., and the St. Regis formation 1000 ft. I mention these three sub-divisions because they are more particularly the ones traversed by the Bunker Hill lode. The Burke formation consists of a variety of rocks ranging from nearly pure quartzite to silicious shale. The frequent ripple-marks indicate that sedimentation took place in shallow water. The Revett formation is more homogeneous and consists almost entirely of a hard, clean, thickly bedded quartzite. The St. Regis is composed of shales and sandstones, and some beds of quartzite, all these members showing marked resistance to erosion and therefore making conspicuous outcrops.

The geologic relations of the Bunker Hill lode are described in the report as follows: "All the ore of the Bunker Hill & Sullivan, Last Chance, and Sierra Nevada mines lies in fine-grained sericitic quartzites thought to belong to the Revett formation. The orebodies are definitely related to a persistent fissure which strikes N 45° W and dips to the south-west at an average angle of 38°. Both strike and dip, however, show considerable local variation. This fracture, locally known as the 'foot-wall fissure', in this report is called the Bunker Hill fissure. It has been traced almost continuously from the Sullivan claim, on the east side of Milo creek, to a point about 200 ft. down the west slope of the ridge between Wardner and Deadwood gulch. . . . The fissure has all the characteristics of a considerable fault; but the walls are lithologically identical and whatever faulting has taken place has not perceptibly affected the structural relations of the rocks at the surface. . . . So far as ore deposition is con-

cerned, the Revett quartzite found in the Bunker Hill & Sullivan and Last Chance mines may be regarded as homogeneous material. The formation of the orebodies appears to have been conditioned by fissuring and the deposition of the ores exhibits no observable relation to bedding-planes, nor is there anything to suggest that, within the general zone of mineralization, particular beds have been more favorable than others to the accumulation of ore. Details of folding may thus be eliminated from economic consideration. The only eruptive rock known in the Bunker Hill & Sullivan and Last Chance mines is a much altered greenstone dike which is exposed at the half-way switch in the Kellogg tunnel. The dike is about 50 ft. wide and may have been a diabase or a diorite. . . . The dike is far in the foot-wall country and apparently has no connection with the orebodies, which are found only in the quartzite of the hanging wall.

"The Bunker Hill fissure is well defined throughout the productive parts [of these mines] and is usually recognized with ease. . . . There is almost invariably a thin seam (1 or 2 inches) of tough, nearly black clay gouge which usually shows two or more planes of movement and slickensiding. According to Mr. Easton, this gouge contains lead and manganese. Under this seam is a white, creamy, or buff band, ranging from a few inches to a foot or more in thickness, of crushed quartzite which in places is so finely powdered as to form what is usually termed sugar quartz. The white band contrasts strikingly with the black clay seam. . . . The sugar quartz usually passes gradually into the less-disturbed foot-wall quartzite. On the hanging-wall side the black seam is in some places in contact with ore, in others with shattered but barren quartzite.

"Although the quartzite of the foot-wall has been well explored, all the ore so far found. . . . has lain in the hanging wall of the Bunker Hill fissure. That no ore should have been deposited beneath the persistent seam of dark gouge characteristic of this fissure is remarkable, as the quartzites³ of the foot-wall are identical in character with those of the hanging wall and are in places extensively fissured and broken, though usually less so than in the hanging wall. In the hanging wall, in addition to much irregular fracturing, two sets of fissures may be distinguished, one approximately parallel to the Bunker Hill fissure and the other nearly at right angles to it.

"The zone of fissured quartzite in which the orebodies occur has a maximum width of 300 ft., measured perpendicularly to the Bunker Hill fissure. Within this zone, here in contact with the foot-wall, there separated from it by barren quartzite, are numerous irregular orebodies, usually without definite walls or boundaries. Locally, however, the ore may be bounded on one side by the clay gouge of the Bunker Hill fissure or on one or more sides by some of the subsidiary hanging-wall fissures. . . . It is difficult to convey a satisfactory idea of the dimensions of orebodies so lacking in regularity. Individual pay-

³Which of the "quartzites"? We have been informed that the lode is in one formation, the Revett quartzite.

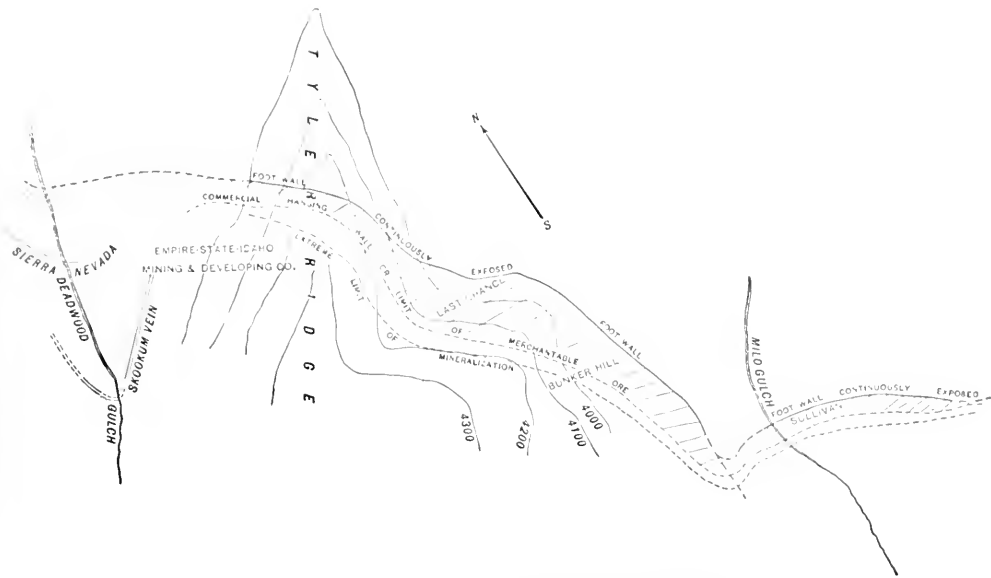

FIG. 1. PLAN OF THE BUNKER HILL LOPE. By J. R. Finlay

FIG. 2. STEREOGRAM SHOWING THE GENERAL RELATIONS OF THE PRINCIPAL FISSURES AND ORE-SHOOTS OF THE WARDNER GROUP OF MINES. By F. L. Ransome

shoots may be 500 ft. in length, 100 ft. or more in width, and 300 or 400 ft. in depth. The whole fissured zone, 300 ft. in width, may, in a broad sense, be regarded as a single great lode, within which the partly overlapping and partly connected orebodies are not uniformly distributed in the plane of the zone but are grouped into at least four fairly distinct shoots."

Then follows a brief description of the several ore-shoots. I shall quote only one paragraph more.

"The orebodies of the Bunker Hill & Sullivan mine are usually of entirely irregular form and the longest diameter of the body may lie at any angle with the Bunker Hill fissure. The absence of definite limiting walls to the ore is a characteristic although not invariable feature of these large bodies. Masses of nearly solid galena grade outwardly into ore containing larger proportions of gangue and finally into barren country-rock. Here and there, however, the ore ends abruptly at a fissure whose walls show evidence of some movement since a part at least of the galena was deposited. Such a fissure, for example, forms a local hanging wall to part of the large March orebody on the Kellogg level. Similar fissures in some places traverse the orebodies, and the ore forming their walls is usually slickensided. Nowhere, however, are the fissures important faults. Some orebodies rest directly upon the foot-wall of the Bunker Hill fissure and are slickensided, showing that movement along this fissure has continued since the ore was deposited."

This geologic diagnosis shows but little advance on that of Mr. Finlay, despite the much greater facilities for investigation and research available to the gentlemen of the Survey. Both describe a wide zone of shattered quartzite adjoining a strong fissure, from which the orebodies extend irregularly into the hanging-wall rock. The important part played by a number of other fault-fissures is not recognized, and it cannot be said that the scientific information published by Messrs. Ransome and Calkins was of any practical value to the management of the mine. Fortunately, further geologic guidance was forthcoming from another source. An apex suit between the Federal Mining & Smelting Company and the Bunker Hill & Sullivan Mining & Concentrating Company called for intensive investigation of the local geology. For this purpose, the Bunker Hill company engaged Oscar H. Hershey in the fall of 1908. He proceeded forthwith to make a geological map of the area, about 3 by 4 miles, called the Wardner quadrangle. Mr. Calkins had examined this area, but not to his own satisfaction, for he says: "The structure is most complex and also most obscure in the quartzitic rocks near Wardner. Here the mapping must be considered as greatly generalized." It was; whereas Mr. Calkins identified five faults within this area, Mr. Hershey identified and named no less than 40, and recognized others of minor importance. This was the result of six weeks of steady work. He published¹ the map embodying his observations in 1912, after the

lawsuit was ended. With the map he gave a description in which the principal rock formations traversed by the Bunker Hill lode are given as follows:

	Ft.
St. Regis	1000
Upper Revett	900
Middle "	100
Lower "	1300
Upper Burke	2000
Lower "	1500

It will be noted that this makes a total of 5800 ft., as against the 4200 ft. in the general section of the U. S. Geological Survey. Mr. Hershey estimates the total thickness of the Algonkian system at 19,800, as compared with the 17,200 ft. of the Survey. Such igneous rocks, in dike form, as he has noted in the district have, he says, "no apparent genetic connection with any ore deposit and are probably much younger than most of the ore". So they play no part in the discussion, which is concerned chiefly with the faulting, and later with the source of the mineralization either in the sedimentary beds from which the quartzite series was formed or the suspected underlying mass of igneous rock.

Mr. Hershey continued his survey of the Wardner district and by 1909 he had mapped 97 faults. His work underwent competent criticism, without suffering in the process. In 1916 J. B. Unpleby and E. L. Jones Jr. of the U. S. Geological Survey undertook to re-map this area, but they encountered so many difficulties, chiefly that of discriminating between the formations, that they dropped the project. I take pleasure in reproducing Mr. Hershey's map, which is a record of careful and intelligent investigation, of a kind only too rare.

We have seen how previous observers had emphasized the Bunker Hill fissure as the main line of departure for the mineralization. Mr. Hershey identified this 'Wardner foot-wall', as it was known locally, with a fault named the Lower Gate. Eastward and downward it diverges from the foot-wall of the lode and crosses it to the hanging wall. In large part it is roughly parallel with an older fault, into which it merges in places. Both faults were disclosed in the lower workings of the mine, so that Mr. Hershey labeled the upper fault the Upper Gate and the younger and lower one the Lower Gate.

A feature stressed by Messrs. Ransome and Calkins, as well as by Mr. Finlay, was the absence of a definite hanging wall. Indeed, the courts, in the course of apex litigation, adopted this idea. For example, in *Last Chance v. Bunker Hill & Sullivan*, 131 Fed. 579, the finding of the Master was "that the Bunker Hill lode has no physical hanging wall, no marked line complement to the foot-wall, in defining the limit of the fissure; that for its underlying boundary it has a well-defined, continuous bed of quartzite, but for its overlying boundary it has only an irregular and vague outline of the limit of mineralization, from which fact, and the peculiar geological formation of the lode, it is very difficult to define this limit with any degree of certainty, for which reason much confusion and some contradiction appears in the testimony upon this point; that the weight of the testimony

shows, however, that the mineralization usually fades in value until a point is reached 350 ft. or 400 ft. out, where the rock is practically barren". Of course, the "continuous bed of barren quartzite" constituting the foot-wall is not accepted as a correct description, for Mr. Hershey's map and the evidence obtainable underground unite in proving the contrary, namely, that the lode-channel transgresses the bedding-planes, which themselves are dislocated by numerous faults. It is now known, moreover, that before the limit of mineralization is reached, there is an increase of it, almost to the point of making 'ore', in the crushed rock of the Buckeye fault. This interpretation was adopted by the geologists on the side of the Bunker Hill in the later lawsuit with the Federal company over the Last Chance ground, but the case never came to trial, the dispute being settled otherwise in 1910, the Bunker Hill company coming into the possession of this adjacent mine peaceably. Mr. Hershey was retained as consulting geologist, an appointment that he still holds. This fact would appear to indicate the value set by the management upon his investigations and the advice based thereon. As editor I was glad, in 1912, to publish his treatise on the origin and distribution of the silver-lead ores in the Wardner district in the form of three successive articles,⁶ which were re-printed in pamphlet form. Mr. Hershey summarizes his hypothesis for the origin of the ore, as follows: "The lead, silver, and zinc minerals of the Wardner district were originally disseminated through certain bands of the Belt sediments; were first concentrated into the visible disseminated zinc and lead deposits through the action of the heat and probably water emanating from a monzonite magma; and were then concentrated into commercial ore-bodies by hot waters that were forced to ascend by the compressive stresses that produced the thrust-faults, these thrusts opening the fissures in connection with which the ores have been deposited. The ores of each successive stage have probably been derived in part from those of earlier ore-forming stages, in part from the visible disseminated deposits, and in part from the original minute disseminations in the sediments."

Against this must be placed Mr. Ransome's hypothesis, as set forth in Professional Paper 62, already quoted. He says:

"The mineralogical character of the ores indicates that the depositing solutions were hot and under high pressure. Fissures . . . are rarely sufficient as channels for ordinary cold underground water to effect the intense local concentration of metals generally distributed through the rocks in quantities too small to be detected by the ordinary methods of chemical analysis. . . Two factors, fissuring and the presence of igneous rock, have been shown to be almost universally present and in most districts are undoubtedly genetic conditions of prime importance. Other determinative factors are to be found in the character of the country-rock and in its attitude or structure, especially with reference to intrusive masses.

In view of these general and preliminary considerations, the possible relation between the Coeur d'Alene ores and the intrusive masses of monzonite . . . invites attention."

These are shown on the geological map, but as the nearest of them is eight miles from Wardner and the distribution of ore "shows no obvious symmetry" with reference to them, Mr. Ransome acknowledges that they may "appear inadequate to account for" the ore deposition. He points out, however, that the exposures of monzonite represent merely the eroded tops of larger masses that may unite in depth and it is possible that the erosion of a few thousand feet more of rock "would probably expose a large area of monzonite in the central part of the district, with smaller outlying areas where at present no intrusive rock is shown". Here I may interpolate that 'monzonite' is a granitic rock of porphyritic habit, that is, it has a granular texture and is speckled by a characteristic mineral—in this case, feldspar. It is a rock associated with many famous ore deposits, for example, the Utah Copper, at Bingham. Mr. Ransome says furthermore:

"It is not supposed that the ores were derived from the comparatively small bodies of monzonite now exposed in the district. These themselves show some mineralization, as at the Sunset mine, where the monzonite is speckled with pyrite, and they may have entirely solidified before the principal mineralization was effected. The source of the ores is thought to lie in the underlying batholith from which the exposed masses are probably offshoots." 'Batholith' is derived from two Greek words meaning 'deep' and 'stone', and is a term given vaguely to suspected masses of igneous rock underneath the outer crust of the earth. "Underlying" as used by Mr. Ransome is redundant. In developing his magmatic hypothesis—it is hardly a 'theory'—he says that "as there is no thermal activity in the region at present, this magmatic reservoir has probably solidified as a monzonitic or granitic rock. A long period may have elapsed, however, between the cooling of the parts now visible and the crystallization of the whole mass. The occurrence of the Coeur d'Alene ores appears to furnish one more example of the remarkable dependence of mineralization on the intrusion of monzonitic rocks in the Cordilleran region."

After Mr. Hershey had published his paper in the 'Mining and Scientific Press', Mr. Ransome replied to sundry implied criticisms.⁷ He drew attention to the fact that he and Mr. Calkins had been able to devote only a short time to the study of the Wardner district as compared with Mr. Hershey, who had not only their report on which to start his own investigations but also the advantage of continued observation of the exploratory work done in the Bunker Hill mine; and he protested politely against "the probably unintentional disparagement" of the work done by "those who first gave a comprehensive account of the geology and ore deposits of the district". This must have amused many mining engineers who have suffered at the hands, or pens, of the geologists of the

⁶'Genesis of Lead-Silver Ores in Wardner District, Idaho', 'M. & S. P.', June 1, 8, and 15, 1912.

⁷'M. & S. P.', August 3, 1912.

Survey in exactly the manner suggested. The first study of the economic geology of our Western mining districts has usually been made by mine managers and local geologists, who not uncommonly have written papers on the subject for the Institute or for the technical journals. When, in due time, the gentlemen of the Survey have come to a district to make a scientific study of it, they have had the benefit of the pioneer investigations recorded by others possibly less learned but certainly quite as conscientious; they have been enabled to do their work with all the resources of a scientific bureau at their disposal, and they have prepared monographs and professional papers of recognized value, but marred, in my opinion, by an ungenerous treatment of the pioneer investigators whose spade-work has been so helpful to them in driving a scientific furrow of larger scope and greater precision. Long ago John A. Church referred to "the usual self-sufficiency of the officers of the U. S. Geological Survey" and I can recall several instances in which they have referred to the precedent studies of mining engineers only for the purpose of emphasizing minor points of disagreement. Moreover, they have had the habit of frequent reference to the writings of their own confreres while making scant mention of those of non-official geologists, whose writings have been distinctly useful to them in preparation of their more elaborate treatises. Therefore we smile when Mr. Ransome, in this case, acknowledges where the shoe pinches. Mr. Hershey had exactly that advantage, of later and fuller investigation, that is usually the privilege of the Federal geologists, and if he was enabled thereby to criticize and correct effectively, we accept the position as entirely in accord with the eternal fitness of things.

Mr. Ransome re-states his own hypothesis thus: "The fissuring of the district was due to stresses set up during the intrusion and solidification of the great quartz-monzonite batholith of central Idaho, of which the exposed monzonite masses in the Coeur d'Alene district are probably offshoots, and . . . the ore constituents, inclusive of the siderite but probably exclusive of some of the quartz, were given off as emanations from the deep-seated portions of the slowly crystallizing batholith. Among the facts adduced in support of these conclusions was the mineralogical connection, through deposits of intermediate character, of the orebodies of the Wardner type with others in the same region that are genetically connected with contact metamorphic action."

Concerning Mr. Hershey's hypothesis, he says that it is "both novel and ingenious, but while it would be unfair to expect him to marshal all his significant facts [why not?] in a short paper, nevertheless his presentation, in view of the work previously done in the district [and acknowledged to be sketchy], appears deficient in evidence". I shall not discuss further this question of the origin of the ore; it seems to me that the rival hy-

potheses are equally interesting and equally undemonstrable for lack of sufficient evidence; nor does it matter to the miner whether the valuable mineral came from the batholith or from the sediments above that batholith; what the miner wants to know is something about the final concentration of the mineral into masses that he can exploit profitably. This last stage of concentration appears to have been influenced chiefly by structural conditions, in the form of faults and fissures. It is the position and relation of these that Mr. Hershey has worked out with so much pains and success. His map has served as a chart for prospecting in the Bunker Hill mine. The use of it has led to the finding of ore, and thereby it is confirmed as a valuable contribution to the geologic diagnosis of the district.

MINERALOGY. The composition of the ore is important to the metallurgist, to whose work we shall come in a later article of this series. The ore is composed of quartzite enriched by silver-lead minerals. The quartzite consists of grains of quartz cemented by quartz and sericite, together with some secondary siderite. Sericite is a silky hydrous mica resembling tale. Siderite is the carbonate of iron; it varies in color from white to dark yellow. Not only does it exist as a secondary constituent of the altered country-rock forming the matrix of the ore, but it is an important associate of the valuable minerals, that is, those of the silver and the lead. In the Bunker Hill lode the siderite is the principal gangue-mineral, much of the ore consisting essentially of a mixture of siderite and galena, the rich ore containing a major proportion of galena, whereas in the poorer ore the siderite is reticulated by minute veinlets of galena. This structure renders it difficult to separate the valuable mineral, the galena, from the valueless gangue, the siderite, except by fine grinding, as we shall see when the milling process is described. The galena is fine-grained, as compared with that of other lead-mining districts, such as those of Missouri. Some of it is so fine-grained as to be called 'steel galena' by the miners. When it oxidizes, it changes to cerussite, the carbonate. The sulphate (anglesite) is rarely detected in the Bunker Hill ore. A little tetrahedrite, the gray sulphide of copper, has been found in the Sullivan and Tyler workings, but it is rare. Native silver has been found on the upper levels, but the silver that forms so important a product is present in chemical combination with the galena, and therefore is not discernible to the eye. Fine-grained iron pyrite is disseminated throughout the lode-channel and also in the filling of the fault-fissures, but, on the whole, the Bunker Hill lode may be said to be remarkable for its small proportion of pyrite, as compared with other silver-lead deposits. The chief feature is the large proportion of the carbonate of iron. In this respect the Bunker Hill lode is generally regarded as unique, for, although siderite occurs in the lead deposits of Wood River, in the Iglesias district of Sardinia, and in the Linares district of Spain,⁹ it is found sparingly in these localities, whereas at Wardner it constitutes as much as half of the lode-matter.

⁹In Professional Paper 62, he made an interesting comparison between the silver-lead deposits of the Coeur d'Alene and those of the Wood River district, as described by Waldemar Lindgren in the Twentieth Annual Report of the U. S. Geological Survey.

⁹Prof. Paper 62, p. 95.

Mining Exploration

By J. H. FARRELL

SUMMARY. The discovery and development of new mines in the Western mining districts is probably not making good the depletion of ore-reserves in operating mines, and it seems likely that in the near future there must be a marked change in the policy of the larger mining companies in regard to the development of prospects.

Exploration companies in the past have done little real exploration or development, having limited their work to the search for developed mines and to mine examinations. Such methods as they have adopted have undoubtedly discouraged prospecting.

State and Federal geological reports do not offer such information as will lead to mine development, and often the publication of such reports is so delayed as to be of no practical value to mine operators.

Owners of old mines and undeveloped properties do not understand the necessity of having complete reports in order to get proper consideration from examining engineers, and it is exceptional to receive accurate and convincing data on such properties.

In conducting successful operations for a development company, the first step should be to make detailed geological surveys in a few districts of proved productivity.

The best development opportunities determined in this way should be thoroughly tested by drilling or by underground work.

Increased incentive to active effort should be obtained by profit-sharing arrangements with the men who carry on the field-work.

The chief requirement for success is that the development company must 'dig' in addition to examining mines.

INTRODUCTION. The discovery of mineral deposits has been a most important factor in bringing about the exploration and settlement of new regions. Michigan and Montana, California and Alaska, would be decades behind their present stage of development had there been no metallic wealth to attract the pioneer. Men went to the new districts and bore the hardship and risk because of the chance of becoming wealthy through successful effort.

Our country has proved so rich in natural resources of all kinds that little thought was given in earlier days to either conservation on one hand, or systematic development on the other. It was rather taken for granted that these resources were practically inexhaustible, and might be made to yield to any methods of exploitation. But in the last few years questions have arisen.

How about the richer iron ores, those which can be sent direct to the blast-furnace? The supply does not look as adequate as it did five years ago. The answer to this question is that there are deposits of low-grade iron ores much more extensive than those of the higher grades now being mined; and these 'lean' ores can be mined and con-

centrated by known methods even in competition with the 'direct shipping' ores.

What of the copper supply when the present great producers, especially the 'porphyry' mines, are exhausted?

Where are we to maintain or increase our production of gold and silver?

The answer to these questions, and I shall try to show why it is the right answer, is more digging.

CONDITIONS IN THE PAST. When California was a new country much gold was won from placer deposits by men whose capital consisted largely of brawn and courage; and many of these men and much of their gold went into the development of 'quartz' mines, until the State became the greatest gold-producing region in the world.

Prospectors traveled eastward into the Sierra and worked their way into the desert country on the other side of the high mountains, and each season saw the location of new mines, and the beginning of new 'stampedes'. It was easy to get help in the opening of bonanza deposits, which required relatively little capital expenditure and yielded rich returns. But as the bonanza deposits grew fewer, and more complex methods were required to treat the ores, mining passed from the control of individuals into the hands of the larger mining companies. Technically trained men were placed in charge of operations and mining was put upon a 'more scientific basis'. This change had bad phases, along with much that was unquestionably good.

At college we learned the theory of sampling and estimation of ore in mines. We often heard it stated that mining had been reduced practically to a manufacturing basis. In most cases mining engineers were placed in charge of the work of finding new mines; these men had been trained from the start of their professional careers to believe that mine examination is an exact science. They calculated tonnages, value, recovery, working cost, capital requirements, and so on, and decided whether a certain mine could be operated at a profit.

Nowadays the engineers usually decide that the mine cannot be profitably acquired or operated.

The system involving analyses and tape-line decisions is successful in a field where there are developed mines to examine; and there were many such mines at the close of the first period of Western exploitation; mines from which the higher-grade ore had been taken, mines containing ores that could not be treated successfully by old processes, and mines that were made more accessible by improved transportation.

For several years the examining engineers made important finds, and much money for their clients, and some for themselves, until the supply of developed mines began to fail, both in the United States and in the wonderfully

rich Mexican districts. During this period the prospector had a hard time of it. He found a decreasing number of bonanzas, which would attract men willing to gamble on prospects; and a decreasing number of men ready to take prospecting chances. The engineers in charge of 'exploration' for the big mining companies could not be interested in prospects. Their instructions were to find developed mines.

From the copper and iron ranges of Michigan there came men of a more practical type, who undertook successfully the development of some properties from the prospective stage in Arizona. A little later came the most notable development of recent years, that of the low-grade, or 'disseminated', copper deposits, often referred to as the 'porphyry coppers'. Everyone started to look for such mines, and several important discoveries were made. But, although these resulted in greatly increased copper production, and temporarily brought mine development abreast of depletion, they did not help prospecting or exploration work greatly. Formerly, the cry had been: "We must have developed mines." It changed to, "Find us porphyry coppers, or developed mines."

The inventor had been told for many years. "There is practically no risk in taking over a developed mine, where the grade of ore, cost of handling, and profit, can be accurately determined." To this was added the statement, "The low-grade 'disseminated' or 'porphyry' copper deposits offer very large tonnages of ore, which can be cheaply proved by drilling. The subsequent mining and milling are more in the nature of a great manufacturing industry than ordinary mining."

So much for a sketchy description of mine development, and the decline of prospecting in the Western States.

CONDITIONS TODAY. Where are the new mines to be found in the next ten years? We are now a creditor nation, and there should be ample funds for mine development along with other enterprises. Are we to look to Asiatic and South American districts for promising fields? Mexico, of course, has been beyond consideration, and must remain so as long as that country is afflicted with the prevailing chaotic conditions. It is likely that there will be more activity than ever before in foreign fields on the part of American capital, but it does not follow that our resources at home need be neglected.

Let us see what the present situation is.

There are in California, for instance, many regions which have not yet been adequately explored, even by prospectors; there are others which were discovered fifty years ago and which have been almost forgotten. Prospecting no longer appeals to as many men as it did in the past, because the chances of rich surface strikes are necessarily less, and it is much more difficult to get assistance in developing claims.

There are many old mines held idle by estates or heirs who cannot, or will not, work them, and will not sell on reasonable terms. In many cases no reports are available, because owners do not understand the necessity of having accurate and well-presented reports in order to ensure proper examination by engineers representing possi-

ble purchasers. In many districts there are a few more or less discouraged old-timers waiting around for the camp to 'come back'. They hold most of the ground by right of location and annual assessment work, or, in most cases, by re-location and prehistoric assessment work. But these men do not, as a rule, ask excessive prices, and they do know the ground.

THE EXPLORATION COMPANIES. On the other hand are the so-called exploration companies, which do not explore. At least they do not often explore in the sense of sending men or parties into unknown fields to search out mines; they do not usually explore in the sense of doing work on promising outcrops; they do not usually explore by doing new work in the mines examined. What they do, is to examine mines, inspect their workings, sample, scrutinize costs, and determine whether the property under consideration can be purchased without taking any chances on further development. If developed mines are not offered to these companies, their engineers do little but draw their salaries, travel about the country, and keep the executive offices advised as to activities in the various districts they visit.

In many instances no field-work is done; the head of one exploration department made substantially the following statement: "Of course, when I say that we examined over a thousand offers, that does not mean that my men actually visited the properties. By far the greater number were eliminated in the office, merely by reading and studying the reports submitted by the owners or promoters."

Too much "exploration work" is done in that way. An office is unquestionably more comfortable than a shack in a deserted camp; and a swivel-chair is more appealing than the saddle, after a certain stage in life is passed.

Mining engineers are not entirely to blame for the fact that they do not explore or prospect. The men in control of the companies, who usually have little knowledge of field conditions, often impose restrictions that make it impossible for the field-engineer to be anything more than an interested observer. First of all, there is the old demand for developed mines; next, the requirement of large tonnage; one company wants only a smelting ore; another requires ore that will cyanide readily. But the outstanding fact is that the field-engineer cannot do any real mining; he is only there to examine and report. Of course, he draws a satisfactory salary for such work, and if he does not find any mines, he at least builds up a reputation for level-headed conservatism, and finally his function is to prevent the optimistic capitalist from taking any chances with his money!

PUBLICATIONS AND REPORTS. What information is there available to guide the field-engineer in his search?

The U. S. Geological Survey reports are hopelessly general in their descriptions, and their authors, as a rule, carefully refrain from expressing any opinion that might encourage development work. Besides, by the time the final report on a district is published, it is too out-of-date to assist the operator; in some cases districts have been

developed, worked out, and abandoned, before the publication of the Survey's report.

Much of the work in the Western States has been in the nature of hurried reconnaissance, which frequently does more harm than good because the mapping is necessarily sketchy, and may give false impressions of the territory covered.

State surveys are usually modeled upon the U. S. Geological Survey, and the same mistake, of covering too large an area, is often made.

Both State and Federal Surveys concern themselves more with purely scientific problems, and are inclined to neglect those of direct economic importance. The argument is that detailed mapping and sampling cannot be carried out, because it would take too long, or because the owners of mines or prospects would not permit it. In my opinion, greater aid would be given to mining by more complete reports and fewer of them.

As to reports furnished by owners, it is amazing to see the number of utterly worthless documents, supposed to be descriptive of mining properties. How otherwise intelligent men will utilize such material in the endeavor to interest a purchaser, is an inexplicable mystery. The owner usually argues that there is no use in having geological surface and underground maps because they are of minor importance compared to the tonnage of ore in sight, and the statements concerning it which are made in the report. He also maintains that there is no reason to have the property carefully sampled because the purchaser will not accept such sampling in any event. Accordingly he tries to sell his mine without having any idea as to the actual value of the property, or the conditions that exist upon it; and he fails to realize that the plainer the conditions are made to the examining engineer, the better is the chance that the property will be carefully considered. Nor does the average owner consider the fact that by doing a little carefully planned development work he may make the mine look very much more valuable to the examining engineer.

SYSTEMATIC DEVELOPMENT. Much of the foregoing is destructive criticism, and as such will do little to assist the cause of future mining exploration, unless an attempt is made to outline methods of field-work that will be better adapted to the attainment of practical ends.

Anyone who would find a new mine should decide to spend as much time as possible in the field and as little as possible in his office reading reports.

It should be recognized at the start by the men who wish to spend money to find mines, that merely looking at properties will not bring satisfactory results. The organization which undertakes field-work today should not be an 'exploration company'; the name has unfortunate connotation, and should be discarded in favor of the term 'development company', with the implication that the company is formed to dig rather than look. The field-work should be organized more along the lines of a railroad survey. The Chief Engineer goes into the field and directs the location work; he is followed by the young engineers who attend to the routine work of running

curves and cross-sectioning. Similarly, the Chief Engineer of the development company should determine what districts are to be covered by his corps, and what lines are to be followed by the field-work. Then the junior engineers can carry on the work of sampling and geologic survey, which forms the basis for development work.

It is evident that most of the promising areas are known, within which important mineral deposits may be expected to be found in the Western States. The best districts in which to look for new mines are doubtless those in which valuable orebodies have been mined in the past, and intensive examination, based upon geological study, is most likely to produce results.

DIGGING NECESSARY. But it should be emphasized here that no amount of examination, based on geology or anything else, will find mines unless it is accompanied by digging.

It is true that we have learned many things about ore deposits in the last thirty years, but there are many more things that we have yet to learn. A geologist studying an outcrop can outline various possibilities—sometimes probabilities—but it takes digging to prove the case. It is most dangerous to pick up a treatise on metamorphism, or geochemistry, read up a few theories and recitations, and then go out into the hills and try to tell how it all happened. We are so proud of our new science that we are likely to forget that it pays to dig in order to verify it.

The sites of some of the most important discoveries of recent years prove that known productive areas are worthy of careful consideration, and aggressive development work. As instances of this there are the United Verde Extension and the United Eastern mines, both found in districts where strong companies have been mining for many years. The Divide district is close to Tonopah, and the Tonopah companies sent engineers all over the country in search of new properties, but they would not spend money for development near home. The great discovery was made by a man who insisted on digging, in spite of adverse opinions.

Field-work should be concentrated in a given district until the field-engineer is thoroughly familiar with local conditions. There is little to be gained by sending engineers hither and yon, to spend a day or so looking at a particular property in each locality. An old prospector once calculated that in 35 years in the hills he had spent ten chasing his burros; similarly, the average 'scout', or field-engineer, might estimate his time spent on sleeping-cars, or at least in traveling to and from different places.

On a trip to look at a certain mine, little knowledge can be gained of the district as a whole, and that little will probably be entirely superficial. On the other hand, when a district, or a mine, has been carefully studied, it usually is found that there are several interesting development possibilities; and when these have been determined, it is time to start digging to see what they are worth.

The objection will be made that it is risky and expensive to carry on such a campaign. The answer is that

such work has been justified by the results wherever it has been attempted on a proper scale. It is only by drilling in promising areas that new oilfields are discovered. In the Mississippi Valley lead and zinc districts, drilling for the extensions of known deposits, or in new districts where the geological conditions are favorable, is the only method of finding new mines, because there are practically no surface indications of the deposits. Such development risks must be taken in the Western districts if new deposits are to be found; and by working systematically on a number of such development projects the chance of success is greatly increased, and one success will pay for a large number of failures.

BIG TONNAGE WITHOUT DEVELOPMENT. Many 'exploration' companies in the past have refused to take over partly developed mines because they were "not big enough".

"What we want," said the director of one of these concerns, "is a mine that we can operate for ten years, mining 500 to 1000 tons per day. And we are willing to pay \$5,000,000 for a developed property. We do not want small mines, nor can we waste time on prospects."

But someone must develop a prospect before a big mine can be made; and no man can look at an outcrop, or a partly developed mine, and say certainly that there is no chance for a big mine. Sometimes the chances seem very much against it, and sometimes one can be practically certain there is no chance. But in many cases there is at least a certainty of profitable operation on a small scale, with good development possibilities.

Many good mines have outcrops that would scarcely be looked at twice, had not some persistent old-timer kept hammering away until he struck it rich.

PERSONAL INCENTIVE. In earlier times the incentive to prospecting was stronger because the individual had a better chance of getting assistance in working a prospect. Today the field-engineer is a salaried employee, who has little chance to get more than his salary if he does find a mine. He may have an opportunity to buy stock to the extent of his resources, but that is all. It is true that this makes for extreme conservatism; it is nearly always safest to report adversely or ambiguously, but adverse reports do not lead to mine development.

More mines would probably be found if the engineers of the development company were permitted to participate in the profits from the enterprise.

How about participating in the losses?

That is something that an engineer holding an executive position always does, if he has charge of an unprofitable operation; and he does so whether he is working for a salary or not. No man of sufficient experience to hold such a position will recommend taking risks that are not amply justified.

LAKE SUPERIOR PRACTICE. No originality can be claimed for the points outlined above. The general method has been in use for many years in the greatest mining district in the country.

The system of mine development in use in the Lake Superior district requires preliminary geological work to

determine the more favorable lines to follow in prospecting; the next step is to verify the results of the initial survey as far as possible by drilling; and the third step is to check the drilling by mine-workings.

It may be argued that drilling into sedimentary formation for iron deposits is much more certain of favorable results than drilling for copper, gold, or silver ores. This is not so evident as it at first appears; the iron-bearing formation does not carry a uniform bed of ore, and orebodies of commercial grade are often much localized, with the result that many blank holes are drilled.

In favor of successful development of Western ore deposits, is the fact that much more may be told from the outcrops, especially in the semi-arid, or desert regions. Similar methods were adopted in the development of the great low-grade copper deposits also; but so far there has been no general application of such a plan of development to other types of deposits in this region.

I do not imply that Lake Superior exploration methods would necessarily be successful in the Western mining districts, but it is certain that in many cases astonishing results would be obtained by well-directed and aggressive development work in areas where there has been little activity since the easily discovered superficial orebodies were exhausted. To name even a few of the districts where such work should be done, and to describe in a general way the existent possibilities, would require a series of separate articles.

It is certain that new mines will only be made by the adoption of such a policy of adequate development work, or briefly: **MORE DIGGING.**

'MANJAK' is a term applied to a variety of bitumen or solid hydrocarbon occurring on the island of Barbados, and in Utah, Cuba, and Trinidad. The deposits on the last island are found within a distance of three miles of San Fernando, the second largest town on the island, and within three miles of the famous asphalt lake. In chemical composition, manjak is like asphalt. It is almost pure bitumen. Its melting point is, however, more than 400°F., whereas asphalt melts at 100°F. In composition, it consists of 80 to 90% carbon, the balance being chiefly hydrogen, with a small quantity of sulphur. It resembles coal in appearance, is odorless, hard, and brittle. It is found in thin beds between layers of clay. The most important use of manjak, and one wherein it has won a reputation for saving money, is in connection with rotary drilling for oil. A soft compound is used on the joints of the pipes between the casing threads and drill stem threads, and this prevents either water, sand, or grit getting into the threads, thus preserving them from being stripped or worn off. It not only acts with particular efficacy in keeping such pipes water-tight, air-tight, and free from corrosion at the joints, but it also facilitates the work of joining and separating the pipes owing to its lubricating qualities. It has been found much superior to white lead or any other substances previously used for such purposes, and its use results in economy.—U. S. Bureau of Mines.

Statistical Review

Production of Base Metals for 1919*

Alaska

GENERAL.—Alaska's developed mineral deposits are chiefly gold and copper; hence her mining industry in 1919 was subject to the same depression that affected gold and copper mining throughout the world. This fact explains in large measure why the value of Alaska's mineral output in 1919 was only about \$18,850,000, according to the preliminary estimate of Alfred H. Brooks, while that of 1918 was \$28,254,000. This is the smallest output of any year since 1910. The value of the annual

worse than ever. These conditions have tended to discourage those who were planning new ventures.

Alaska's Mineral Products in 1919

Gold	\$9,000,000
Copper	8,400,000
Silver	650,000
Coal	350,000
Lead	100,000
Tin	50,000
Platinum, palladium, quicksilver, petroleum, and gypsum	200,000
Total	\$18,850,000

PLACER-MINING.—During 39 years of mining, Alaska has produced gold to the value of \$311,000,000, and \$218,000,000 of this amount is to be credited to her placer-mines. There was less placer-mining in 1919 than in 1918, and the outlook for a revival of the industry as a whole under present economic conditions is not hopeful. In the following table a comparison is made between the placer-mining industry in 1919 and in 1918:

Alaskan Placer-Mining in 1918 and 1919

	Summer		Winter		Value of output
	Mines	Miners	Mines	Miners	
1919	420	2100	65	275	\$1,750,000
1918	574	3000	153	613	5,900,000
Decrease in 1919	154	900	88	342	\$1,110,000

A most unfortunate effect of the decline in gold, especially in placer mining, is the discouragement of the prospector. Though many prospectors devote their attention to the search for copper and other minerals, they as a class are held to their vocation by the hope of finding rich placers which they can develop by individual effort.

Gold-dredging continues to hold an important place in Alaskan placer-mining. In 1919 there were 28 dredges in operation for the whole or

part of the season; they produced gold to the value of \$1,000,000, compared with an output of \$1,425,000 worth of gold by 28 dredges in 1918. Two of these dredges were operated in 1919 in the Fairbanks district, two in the Iditarod district, one in the Birch Creek district of the Yukon basin, one in the Georgetown district of the Kuskokwim basin, and the rest on Seward Peninsula.

The Yukon placer districts are the most isolated of the important Alaskan mining districts and are therefore the places where the cost of mining is highest, so that they are the most sensitive to present conditions. This fact is reflected in the comparison of their gold output for 1919 and 1918, made in the subjoined table. Fortunately the loss in the Yukon was in part offset by a somewhat greater production of gold at the placer-mines on Seward Penin-

MAP OF ALASKA

output of gold from Alaska declined from \$16,700,000 in 1916 to \$9,000,000 in 1919. The Alaskan gold-mining industry is particularly sensitive to present conditions because many of the enterprises were not on a very sound economic basis; gold production has been kept up for many years by the exploitation of bonanza placers rather than by the systematic development of large deposits of lower grade.

Except for the railroad construction during the year, the transportation conditions in Alaska have been worse in 1919 than in any previous year. The coastal steamboat service has been unable to meet the demand for freight and passenger transportation, and the river steamer service on the Yukon and its tributaries has been

*From preliminary reports of the U. S. Geological Survey.

sula, where considerable activity on a comparatively large scale is recorded.

Placer-Gold Output of Yukon Districts, 1918-1919

	1918	1919
Fairbanks	\$800,000	\$770,000
Iditarod	1,240,000	725,000
Tolovana	875,000	525,000
Ruby	400,000	150,000
Cross-Creek-Crocker	175,000	115,000
Hot Springs	150,000	105,000
Koyukuk	150,000	100,000
Marshall	150,000	100,000
Imukok	120,000	60,000
Fortymile	75,000	40,000
All others	129,000	140,000
	\$1,264,000	\$7,830,000

The placer-gold output of the Fairbanks district was produced by 36 summer mines employing 360 men, and 20 winter mines, employing 80 men. Drift mining is on the wane at Fairbanks, for in 1918 there were over 40 deep mines and in 1919 there were only 28. Mining in the Iditarod district, except that done by the dredges, is decreasing year by year. Much of the rich placer ground has been worked out, and the isolation of the district, with the consequent difficulty of obtaining labor and the high freight rates, has not encouraged the exploitation of the placers of lower tenor. The same is true to a great extent of the Tolovana district, where most of the mining has been done by underground methods, but some shallow placers in this district can be developed when operating costs are reduced. Nothing of importance was done in the Hot Springs district.

Except for the discovery of another pay-streak on Poorman creek there was no important advance in the Ruby district during 1919. Placers were discovered on the Hogatzka river, in the Koyukuk district, in 1919, but they have not yet been sufficiently developed to determine their value. Placers are also reported to have been discovered in the Birch Creek basin, tributary to Wild river, and also in the Koyukuk district, though these reports have not been verified. These placers are in inaccessible regions and would have to be very rich to justify their development under present conditions. These reports, however, indicate that not all the Alaskan prospectors have become discouraged. The gold production from the Marshall district has been maintained by the output of a few mines working on comparatively rich placers.

Seward Peninsula was the most prosperous of the Alaskan placer-mining regions in 1919; it produced gold to the value of \$1,300,000, compared with \$1,108,000 in 1918. A total of 21 gold-dredges were operated, distributed as follows: 8 in the Nome district, 8 in the Council district, 4 in the Solomon district, and one each in Kongarok, Fairhaven, and Port Clarence districts. In addition to the dredges, about 70 open-cut mines and 13 deep placer-mines were operated.

GOLD-LODE MINING. Eighteen gold-lode mines were operated in Alaska in 1919 and produced gold worth about \$4,100,000. Twenty-five mines were operated in 1918 and produced gold worth \$3,473,000. The increase in 1919 came from the three mines at Juneau, but does not assure the continued prosperity of the lode-mining industry, for these mines at Juneau are working on too small a margin to make it certain that they will be able

to pay the continued increasing expense of mining. The only other large gold-lode mine in Alaska is in the Sitka district, where operations in 1919 were, so far as known, on about the same scale as in 1918.

The most important event of the year bearing on lode mining in Alaska was the development of some large ore-bodies in the Stewart River basin of Portland Canal, which marks the south-eastern boundary of the Territory. So far as known, the only properties developed sufficiently to prove the value of these bodies are on the Canadian side of the International boundary, close to it. The same geologic conditions occur on the Alaskan side of the boundary, where metalliferous lodes have long been known to occur and where many claims have been staked. The natural seaboard outlet for the Canadian as well as the American properties in the Stewart River basin is the town of Hyder, on the Alaskan side of Portland Canal. The lodes of this district, so far as known, consist of (1) disseminated deposits in fracture zones, and (2) vein filling in well-defined fissures. Excitement has recently been caused by the finding of auriferous lodes carrying large quantities of silver. Galena, tetrahedrite (gray copper ore), pyrrargyrite (ruby silver), and native silver, are said to occur in these ores. There is reason to believe that similar deposits may occur in the Alaskan side of the Stewart River basin.

The small lode operations in 1919, several of them no more than prospects from which a little ore is being taken, are distributed as follows: One each in the Ketchikan, Chitina, and Kenai Peninsula districts; five in the Willow Creek district; and six in the Fairbanks district. The most active prospecting and development of gold lodes in 1919 was in the Willow Creek district, which lies adjacent to the railroad, where, however, no property has yet been opened and equipped on a large scale.

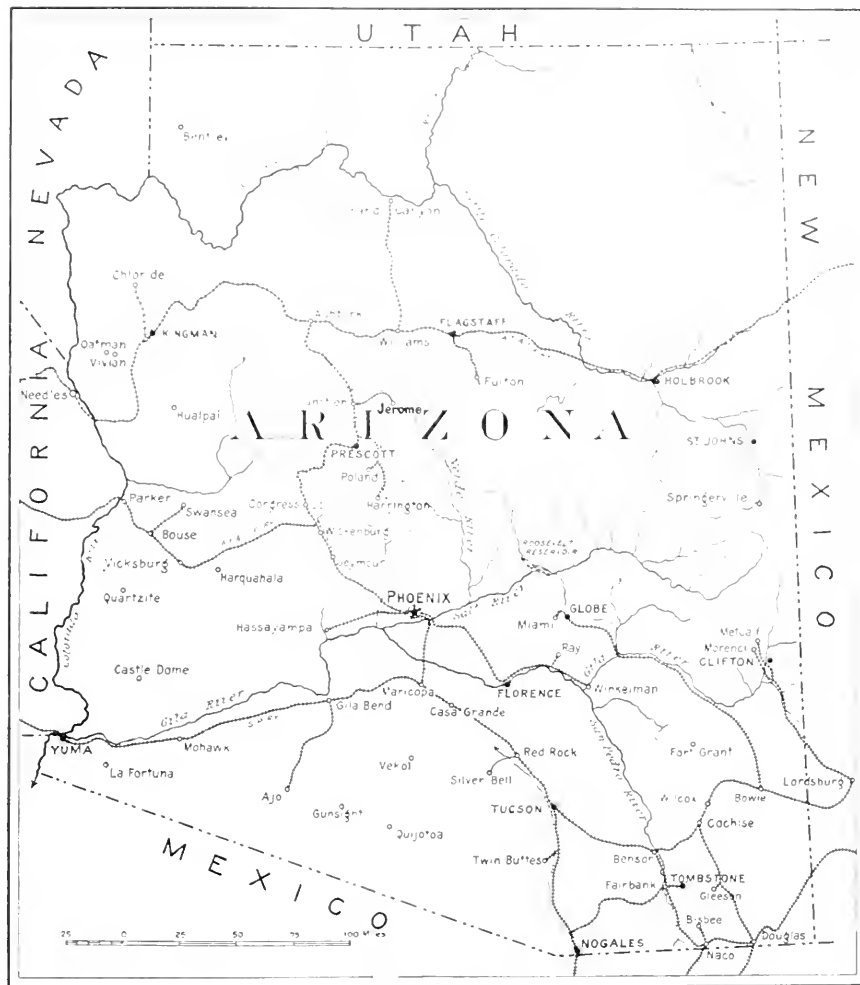

COPPER.—Eight copper mines were operated in Alaska in 1919, producing about 44,800,000 lb. of copper, valued at \$8,500,000. The production of copper in 1918 was 69,225,000 lb., valued at \$17,099,000, and came from 17 mines. This curtailment of copper mining was due to the fall in the price of copper and the uncertainty of the market, as a result of which the larger mines decreased their output and many of the small ones closed down.

Most of the prospecting for copper in 1919 was done in the Susitna basin, tributary to the Alaska railroad. A number of copper lodes of some promise have been found in this region, but they have not been sufficiently developed to prove their value. In south-eastern Alaska the Rush and Brown mine was the largest copper producer. Copper was also produced at the Salt Chuck mine, better known for its output of palladium. The three large mines, Bonanza, Jumbo, and Mother Lode, of the Kennecott group, were the only producing mines of the Chitina district in 1919, though some development work was done on other properties. On Prince William Sound the Beatson-Bonanza and Ellamar copper mines were the only properties worked systematically.

MISCELLANEOUS METALS. Most of the silver and lead produced in Alaska has been won as a by-product in

mining gold and copper. Silver-bearing ore in the form of galena is widely distributed in Alaska, but until two years ago was little heeded. Since then the high price of silver has led the prospectors to search out some of the galena lodes, and as a consequence some promising discoveries have been made. The development of silver-

in 1919, two dredges and one small open-cut mine were operated on placer tin, employing some 25 men. No new deposits of placer tin have been discovered in the York district in recent years, and there is no certainty that this form of tin mining will be continued there when the deposits now being exploited are worked out.

MAP OF ARIZONA

bearing lodes in the Canadian part of the Portland Canal region has already been referred to.

The silver output of Alaska in 1919 was about 590,000 oz., of which some 500,000 oz. was recovered from copper ores. Alaska's lead output of 1919 is estimated to be 800 tons, practically all a by-product of the gold-lode mines.

The York district, of Seward Peninsula, continues to be the centre of the tin-mining industry of Alaska. Here,

Some platinum was recovered in the mining of placer gold in the Seward Peninsula, Tolstoi, and Chistochina districts in 1919, but the quantity is unknown. The mining of copper ores at the Salt Chuck mine, in the Ketchikan district, which carry palladium and platinum, was continued, as in the previous year. There was no production of tungsten, antimony, or chromite in 1919, and development work on properties carrying these minerals was practically stopped. Productive mining was

continued on the quicksilver deposit on the lower Kuskokwim river.

Arizona

The output of gold, silver, copper, lead, and zinc from mines in Arizona in 1919, according to the estimate of Victor C. Heikes, had a total value of about \$108,707,000, a decrease of \$93,427,880 from the figures for 1918. Although there was a decrease in both quantity and value for all these metals, the largest decrease was for copper. During the first part of the year, there was a marked curtailment of output, and in the Verde district labor troubles closed the mines for nearly four months. During the last three months of the year many of the large companies again curtailed production as a result of market conditions.

GOLD. The production of gold decreased from \$5,435,027 in 1918 to \$4,231,000 in 1919. This decrease, \$1,204,000, was a result of the general curtailment in the production of copper ore. More than half the output of gold from Arizona came from the gold ores of the San Francisco district of Mohave county, although there was a decrease from this source as well as from the copper ores. The United Eastern Co. remained the largest producer of gold in the State, and the Tom Reed Co. continued its large output. The Copper Chief mine, in the Verde district, and the Gold Road mine, at Oatman, were idle.

SILVER. The mine output of silver decreased from 6,686,152 oz. in 1918 to 4,927,000 oz. in 1919. In spite of the increase in the price of silver the value of the output decreased from \$6,686,152 to \$5,479,800. The largest producers of silver were the Calumet & Arizona, Copper Queen, United Verde, Magma, and United Verde Extension mines. Outside the copper mines, the largest producers of silver were the Bunker Hill mine at Tombstone and the Commonwealth mine at Pearce.

COPPER. The mine output of copper decreased from 764,855,874 lb. in 1918 to 522,000,000 lb. in 1919, a decrease of nearly 32%. The value of the output decreased from \$188,919,401 in 1918 to \$98,296,000 in 1919, and the average price of copper decreased from 24.7c. to 18.83c. per pound. There was a decrease in the output of each of the smelting plants in the State, except the United Verde Extension smelter at Verde. At Miami the output of the International plant came near the record of 1918. The Shannon smelter at Clifton was closed in January, and the plant at Sasco was closed early in the year. At Ajo the New Cornelia Copper Co. continued the leaching of copper ore, but its output was reduced about 20%. In the Warren district development work opened extensive orebodies on the Denn Arizona ground and on leases on Copper Queen ground.

LEAD. The mine production of lead decreased from 12,503,689 lb. in 1918 to 10,000,000 lb. in 1919. The value of the output decreased from \$887,762 to \$575,000. Large shipments of lead were made from the Shattuck mine, in the Warren district, in spite of the delay caused by a fire on the 800-ft. level in March. In Pinal county

the property of the Ray Silver-Lead Co. produced considerable lead ore, though less than in 1918.

ZINC. The output of recoverable zinc decreased from 2,269,643 lb. in 1918 to 1,717,000 lb. in 1919. The value decreased from \$206,538 to \$125,700. The Arizona Hill-side Mining Co., in Yavapai county, was the only important producer.

Dividends from Arizona mining companies during the first 11 months of 1919 amounted to \$19,841,000, exclusive of those of the Phelps Dodge Corporation, which also operates mines in Mexico and New Mexico. Including the dividends of the Phelps Dodge Corporation, the total was nearly \$26,816,000. The companies that paid dividends were the Miami, Inspiration, Iron Cap, Shattuck, United Eastern, United Verde, United Verde Extension, Arizona Copper, Calumet & Arizona, Magma, Ray Consolidated, Arizona Binghamton, and the Phelps Dodge Corporation.

Washington

The value of the gold, silver, copper, and lead mined in Washington in 1919, according to the estimate of C. N. Gerry, was about \$959,000, a decrease of \$518,000 from that of 1918. No zinc ore was marketed. There were marked decreases in copper and lead, and slight decreases in gold and silver. The copper output in the Chewelah district, Stevens county, was somewhat less, and there was a marked decrease in the shipments of silicious ore from the Republic district, in Ferry county. Most of the ore and concentrate from the mines of Washington was smelted at Tacoma, Wash.; Trail, B. C.; Midvale, Utah; and Northport, Wash. The plant at Grand Forks, B. C., was closed in June, and the smelter at Greenwood, B. C., was idle throughout the year. The lead plant at Northport, Wash., was idle several months on account of the inactivity of the Hercules mine in Idaho during most of the year. The price of silver increased to about \$1.12 per ounce, but the average prices of copper, lead, and zinc were even less than those of 1918.

GOLD. The mine production of gold decreased from \$304,658 in 1918 to about \$280,000 in 1919, a decrease of nearly 8%. Nearly all the gold came from the Republic district, and there was a distinct decrease in ores amalgamated throughout the State. From the Republic district approximately 25,600 tons of silicious ore was shipped during the year, as compared with 42,275 tons in 1918. The mines of the district were closed on October 9, as a result of a labor strike. The principal shippers from the district were the Last Chance, Quilp, Knob Hill, San Poil, and Lone Pine mines. The Quilp mine, which had been idle for years, produced the largest output of gold. The Lone Pine-Surprise-Pearl group, which was formerly the largest producer, was idle during most of the year.

SILVER. The mine output of silver decreased from 310,093 oz. in 1918 to approximately 299,000 oz. in 1919. The value of the output increased from \$310,093 to about \$333,000. Nearly half the silver came from copper ores, and most of the remainder from ores from the Republic

district. The Consolidated Mines Co., in the Springdale district, made several shipments of silver ore.

COPPER. The copper output decreased from 1,922,406 lb. in 1918 to about 1,321,000 lb. in 1919. The value of the output decreased from \$474,834 to \$248,700. The United Copper mine, in the Chewelah district, was as usual the largest producer of copper. Ore rich in silver was mined below the 1300-ft. level, and shipments of crude ore and concentrate averaged about 350 tons per month. Other notable shipments of copper ore came from the Sunset mine, near Index, in Snohomish county, and the Loon Lake mine, north of Spokane, where a new flotation plant was operated.

LEAD. The mine output of lead decreased from 5,271,815 lb. in 1918 to about 1,700,000 lb. in 1919. Most of the product came from the Electric Point property, near Northport, in Stevens county, which was idle most of the year. As the company resumed mining in November, the output is largely estimated.

The only dividend paid by a metal mine in Washington during the first 11 months of 1919 was that of the Electric Point mine, which amounted to \$23,790.

DOMESTIC EXPORTS of mining machinery, exclusive of oil-well equipment, from the United States during November 1919, were as follows:

Destination	Value
Denmark	\$185
France	3,706
Norway	2,233
Spain	918
Turkey in Europe	925
England	205,311
Canada	57,068
Honduras	227
Nicaragua	2,232
Salvador	586
Mexico	135,831
Newfoundland	995
Cuba	2,149
Dominican Republic	8
Bolivia	2,279
Chile	60,072
Colombia	13,514
Ecuador	398
Peru	18,184
China	145
Czechoslovakia	610
British India	100
Dutch East Indies	28,693
Japan	7,014
Siberia	820
Siam	1,025
Australia	1,415
Philippine Islands	10,690
Belgian Congo	580
British West Africa	969
British South Africa	20,191
Portuguese Africa	389
Total	\$579,402

COPPER PRODUCTION in Norway amounts to about 3000 tons in ordinary years, half of which is produced at Sulitjelma and the rest about equally from the mines at Røros, Birtavarre, and Christiansand. In 1918 about 600 tons of copper was produced in the Norske Extraction Works at Fredrikstad. Notwithstanding this latter addition to the ordinary production the total output for the year amounted to only about 2200 tons. Although copper has been selling in the United States cheaper than it can be produced in Norway, owing to the fact that the importation of copper was almost wholly stopped in 1918, the Norwegian output commanded a high price, and on

the whole the copper mines enjoyed a year of unusual prosperity.

Blasting Accidents From Missed Holes

*Accidents caused by missed holes occur both underground and in open cuts. Many of them are avoidable. The following report of an accident, occurring in some open-cut steam-shovel work, in which two men were killed, should serve as a warning in operations where any uncertainty exists about a missed hole and where black powder is being used. The accident referred to occurred in an open-pit copper mine in Utah.

The height of the face at the cut is about 30 ft. Twenty 1½-in. vertical holes 30 ft. deep were drilled at the time and chambered with about 50 sticks of 1½-in. dynamite. They were then loaded with 8 or 10 cans of black powder in each hole and exploded with an electric battery, after which the debris was removed by a large steam-shovel. At the time of the accident the dipper was working on the right side of the cut, the boom being turned to the right. The engineer and craneman were in their places, both being on the right-hand side toward the shot. When the dipper was just starting at the grade, to take a load, a flash was seen, followed by an explosion a few seconds later. Most of the men ran under the shovel, two or three did not quite get out of danger and were slightly hurt. The positions of the engineer and craneman were such that there was no chance for them to escape. The engineer's body was found lying on the cab floor, and the craneman's body was found between the cab and boom beam, both being killed by the fall of blasted rock.

This seems to be a clear case of a missed hole that was exploded by sparks from the steel dipper. One of the pitmen said they all saw a flash and ran for the shovel.

The formation at the surface is full of cracks and crevices; also, the springing of the holes would open cracks. The explanation of the cause of the accident is that, when loading the black powder, some of the powder ran down one or more of these cracks and filled a small opening not far from the loaded hole, at the same time leaving a trail of powder from one point to the other. This explains the lapse of time between flash and blast. Sparks from the dipper just as it reached the powder caused the trouble.

The foreman and the pitmen all say they often see unexploded black powder in small quantities among the rocks, but that no flash has been seen before; also, that this was the first missed hole they have known of, though most of these men have been on the job only a month or two.

This accident emphasizes the necessity of careful search of any place where blasting has been done for evidence of missed holes. In the cases where black powder is used the injection of water would serve as an effective preventive of an explosion.

*From Reports of Investigations, Bureau of Mines.

Detonating Dynamite

Four methods are at present in use for detonating dynamite: the blasting cap in combination with safety fuse, the electric blasting-cap, the delay electric blasting-cap, and the delay electric igniter in combination with the blasting-cap. To these may be added Cordeau, which is a 'detonating fuse', but whose cost is so high as to preclude its use in anything except deep-well drill-holes or similar projects where very large charges of explosives are contained in a single hole. Hence it will not be considered in this instance. Consideration of these on the different points characterizing the ideal method, reveals the fact that, with the same strength of blasting-cap, they are all about equal in securing the full energy from the charge of dynamite in the hole. With the blasting-cap and fuse, it is possible to fire almost any number of holes in succession or rotation. This is a most desirable feature in sinking shafts or driving tunnels, but it is impossible with this method to explode a number of holes simultaneously so that the charge in one hole will aid that in the next. With electric blasting-caps, however, it is possible to fire a large number of holes simultaneously and to have each charge aid the other. This reduces, to a certain extent, the amount of explosives necessary. Furthermore, in using either electric blasting-caps or delay electric blasting-caps, it is possible to fire three successive series of holes in rotation, with one application of the current and without coming back to the breast or scene of the shooting. By using delay electric igniters with blasting-caps crimped to the end in combination with electric blasting-caps, almost any number of holes may be fired in rotation. The blasting-cap and fuse method is undoubtedly lowest in freedom from misfires, for in addition to the possibility of a misfire due to the fuse alone, there is the added risk that some moisture may enter the cap and cause a misfire. This possibility could be eliminated by water-proofing the crimp. Electric blasting-caps are as free from misfires as are electric squibs. The delay electric blasting-caps, which are self-contained units, are of equal value in this respect. The delay electric igniter to which a blasting-cap has been crimped probably ranks, with respect to freedom from misfires, between the electric blasting-cap and the blasting-cap and fuse, for there is a possibility of water entering the crimp and causing a misfire. As far as the blaster's safety is concerned, the blasting-cap and fuse method is the most unsafe of those mentioned, because it sometimes happens that fuse will smoulder along for a considerable time and then re-ignite the powder train, turning what appeared to be a misfire into a serious accident. Again, when lighting a considerable number of shots in rotation, the blaster sometimes fails to make allowance for the time required to do the lighting and get to a place of safety. An accident is often the result. Another disadvantage is that the blasting-cap must be crimped to the end of the fuse. This in itself presents an element of danger. The same thing is true of delay igniters, to which a cap must also be crimped. The electric blasting-

cap and the delay electric blasting-caps are complete in themselves, and are, therefore, free from a similar hazard. With the electrical method, the blaster can be in a place of safety before attempting to fire the blast. If, upon application of the current, the blast does not follow, he can safely return and investigate the trouble, allowing, of course, a few minutes if any delay electric igniters are used in the blast. As far as the effect of poor storage is concerned, blasting-cap and fuse and the delay electric igniter and blasting-cap are about on a par. Blasting-caps themselves require protection from moisture, and the fuse in both cases requires similar protection. Electric blasting-caps and delay electric blasting-caps, being better protected from moisture by the filling in the copper shell, are not open to as strong objections on this point. They are also not affected by ordinary atmospheric warmth or cold weather. In first cost, the blasting-cap and fuse would probably be the lowest, although there is a point at which a given length of fuse would equal the cost of electric blasting-caps under certain conditions. The electric blasting-cap is a little more costly than cap and fuse. The delay electric igniter comes next, and the delay electric blasting-cap is the most expensive of all in first cost.

Methods for Firing Dynamite

Points to be considered	Blasting-cap and fuse	Electric blasting-cap	Delay electric blasting-cap	Delay electric igniter and cap
Full energy from explosive.....	1st	1st	1st	1st
Freedom from misfires.....	3d	1st	1st	2d
Relative safety to blaster.....	2d	1st	1st	2d
Relative resistance to adverse storage..	2d	1st	1st	2d
First cost.....	1st	2d	4th	3d

Summarizing the points mentioned above, the electrical method would undoubtedly be placed first, both for igniting blasting-powder and detonating dynamite, in everything except first cost, and as the first cost might very easily be increased a hundred fold by the amount of explosives lost through misfires or the cost of a single major accident, the conclusion is irresistible that the electrical method of setting off blasts is far superior to any other yet devised.—J. B. Stoneking in 'Du Pont Magazine'.

THE United States produced about 58% of the world's output of tale in 1918 and in addition imported more than 11% of all the tale produced by the rest of the world. As little if any tale was exported, it is evident that the United States is pre-eminently a consumer of tale. Canada is the only competitor for the domestic trade in middle-grade tale. About 12,000 tons, 96% of the tale imported in 1918, came into the United States from Canada. The United States is well supplied with low and middle-grade tale, but lacks high-grade material for use in toilet powder, electric insulators, and gas burners, commonly called lava tips. The tale used for such purposes is imported mainly from Italy and France and, through other countries, from India. Within the last two years a new and interesting source of tale has been found in a large dike of serpentine in Harford county, Maryland.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

COLORADO

DEVELOPMENT AT PORTLAND MINE.—LESSEES ARE ACTIVE AT LEADVILLE.

CRIPPLE CREEK.—The new orebody at the 2300-ft. level of the Portland Gold Mining Co.'s No. 2 shaft on Battle mountain, found in a cross-vein that was entered 100 ft. south of the shaft, contains from 4 to 5 ft. of one-ounce ore. This is the deepest point at which ore has been discovered in the district. The rich ore-shoot at the 2100-ft. level is situated more than 2100 ft. beyond former known orebodies, indicating the possibility of finding new ore on other levels.

The Vindicator Consolidated Gold Mines Co. reports the discovery, at the 18th level in the Golden Cycle, of the Lillie vein, a part of the Vindicator system. Eighteen inches is sampling from \$15 to \$30 per ton and 1½ in. from 5 to 10 oz. gold.

Mine operations have been commenced by the Lincoln Mines & Reduction Co. on the Magna Charta claims on Ironclad hill, which are owned by the Rex, M. & L. Co. The Lincoln company is operating under bond and lease and has constructed a milling-plant on the group.

LEADVILLE.—Lessees of the New Monarch Mining Co., operating through the Lida shaft in Evans gulch, under Breece hill, have opened up a nine-foot vein of lead-silver carbonate ore, and will soon commence shipping. The dimensions of the shoot have not yet been determined either above or below, but from present indications the shot is a rich one and a earload of high-grade material is ready to be loaded. The Lida has been overlooked for the past 20 years and is now held under bond and lease by Henry Schuck and eight associates, all miners, who have been cleaning out the old shaft and drifts and carrying on exploration work since last April. The vein was not reached until after most discouraging work. The shaft was choked with ice from top to bottom, and for a distance of 300 ft. the drift was filled with caved rock and mud. Perseverance was rewarded and the lessees are drifting on the vein that has been proved by a 30-ft. raise, all in ore. Prior to the closing down of the property 20 years ago, a heavy flow of water handicapped operations, but this water has been practically eliminated by the Yak tunnel pumps.

Lessees on the Dunkin No. 2 and 3, on Fryer hill, adjoining the Matchless, are shipping about 400 tons per month of silicious ores containing silver, and about 250 tons of iron-oxide with some silver content.

Exploration work is in progress in the Green shaft

near Sumptown, at the mouth of South Evans gulch. The Green is surrounded by producers, such as the Big Four, Gold Basin, and St. Louis tunnel, and it is expected that exploration work will open up the extension of the veins found in these mines.

Shipments aggregating 150 tons monthly are sent out from the Robert E. Lee, a famous old silver-producer of the Fryer Hill section. The property is under lease to Frank Zaits and associates who are shipping a silicious ore with fair silver content to the A. V. smelter.

MICHIGAN

COST OF OPENING SENECA PROPERTY.—JANUARY OUTPUT.

An idea of what it costs to open a copper mine in the Michigan district and put it on a producing basis may be gained from an examination of the financing of the Seneca company. The company did not have to prospect as it was reasonably certain that ore would be found. Nevertheless it has expended close to \$3,000,000. This covers original cost of property, promotion, operation, and equipment of plant up to date. The lode has been opened at three levels and the ore has been tested by actual mill runs. Some of the original treasury money is still on hand, perhaps \$200,000. Last week the company announced the sale of \$500,000 worth of bonds and a provision for an additional issue of stock, convertible into bonds. This additional money ought to take care of the further financial outlays that are necessary. The company has announced that it already has contracted for a hoisting-plant capable of handling 5000 tons per day. A production of 2000 tons per day will require a stamp-mill of at least eight or ten heads. The present cost of building a modern mill is \$250,000 per head; so that a four-head mill, the minimum of efficiency in operation, must necessarily require an outlay of \$1,000,000. Then there is a railroad which will have to be built to connect the mine with the mill. This will require considerable outlay. However, there is a certain source of income that may be counted upon. The Seneca already is producing copper. This production will be increased regularly as developments continue. It will not be cheap production, but the company easily may secure the continued use of a custom mill. The Seneca may be able to duplicate the history of the Ahmeek, which paid its way without difficulty just as soon as production commenced.

All three mines of the Copper Range group, Champion, Baltic, and Trimountain, showed a slight increase in the

output of copper for the month of January compared with the production for December. Champion led all the others, producing 49,000 tons. This compares with 46,000 for December. It means too that the production of the premier mine in the Copper Range will be approximately 2,000,000 lb. of refined copper for January, for the Champion ore today is averaging close to 42 lb. per ton. This record for the Champion is fully up to expectations. Baltic produced 15,000 tons for January, and Trimountain 14,500, just about the same as for December.

Production of the Mohawk for January was 46,628 tons, compared with 48,603 for December. Production of the Wolverine for January was 20,622, compared with 21,769 for December. Mohawk's output of copper will likely be in excess of a million pounds, however, as the grade of ore was a little better than the average for December. Michigan's output was 4215, compared with 4551 for December.

Seneca will continue making shipments to the Baltic mill as rapidly as service is secured until the stock-pile is finished. The second shipment was made this week. It contained mostly rock from the stock-pile, but included some material that now is coming from underground. The smelter return on the first shipment was 22.96 lb. per ton. The mineral did not dress quite as well as ordinarily.

The Seneca shaft will reach the fourth level this week. The present depth is 2086 ft. At the fourth level there will be some concrete work to do in the shaft for the permanent haulage-way. No drifting is at present under way at the third level in the vein, although both openings show good faces where the work stopped. This lateral work will be resumed in the near future. The openings in the levels above, now working in ore, continue to send up average ore.

Unwatering the Gratiot shaft is under way. Bailers have been started, and the work will be done as rapidly as possible. It is the intention of the management to start sinking the Gratiot shaft immediately. At a proper depth laterals to connect with the new Seneca shaft will be put down to provide ventilation.

MONTANA

ANACONDA COMPANY NEEDS MINERS.

BUTTE.—The Anaconda company is increasing its working force as fast as experienced miners can be secured. There are plenty of men but a scarcity of good all-round miners. Most of the large mines in operation have the sign 'Men Wanted' hung out upon their gates, which is a rarity in Butte.

A 4-ft. vein of 5.2% copper has been found in the Birtha shaft of the North Butte company. This is on the extreme easterly portion of the company's property, within 100 ft. of the surface, and adjacent to the Bullwhacker mine.

The Davis-Daly in January produced 1,192,900 lb. of copper, an increase of 700,000 lb. over December. The skips were put in operation at the Colorado shaft on February 8 and 9, when operations were suspended for

48 hours in order to make the change from the old cages and build the skip-pocket at the collar of the shaft. The company is shipping 100 tons of silver ore daily from the Hibernia mine in the district west of Butte. This ore is going to the American Smelting & Refining Co.'s smelter at East Helena.

The Touloume is shipping 150 tons daily to the smelter. It is stated that the orebody recently opened on the 1200-ft. level is proving to be of good size and grade.

JEFFERSON COUNTY.—The Butte-Elk Park Extension Mining Co., operating at Elk Park, 12 miles north of Butte, is dewatering the shaft and workings on the 400-ft. level, preparatory to resuming sinking where it was stopped by a shut-down caused by the coal strike. Three veins in the upper levels will be prospected while the pumping is being completed; one on the 250-ft. level will be cut on the north side of the shaft, and two will be cut on the 400-ft. level. These three lodes have never been opened underground. It is planned to sink to the 1400-ft. level and develop the 710 acres that the company owns.

HELENA.—The Legal Tender mine is producing steadily, having shipped two cars of high-grade silver ore already this month. One car assayed 169 oz. and the other 479 ounces.

NEVADA

TONOPAH AND DIVIDE OPERATORS INCREASE WAGES.—THE NEW WAGE-SCALE.

TONOPAH.—Labor trouble in the Tonopah and Divide districts as a result of the removal of the 50-cent wage bonus has been adjusted by the operators giving an increase in wages equal to the amount of the bonus previously paid, the commissary to be continued with the operators making a 5% profit. The agreement, which has been ratified by both parties, extends for one year from February 14. The mines of both districts practically had been inactive since February 8, with the exception of those owned by a few companies which continued to pay the bonus. The miners and craftsmen, principally the former, walked out as individuals and many have left the districts, but not enough have gone to seriously interfere with a resumption of operations and it is thought by the operators that conditions will quickly become normal. The Tonopah and Goldfield railroad, over which practically all of the men left Tonopah, reported an abnormal number of outgoing passengers on only the first two days following the walkout, 100 passengers being carried the first day and 51 the second, indicating that comparatively few men went to other districts. The new scale is as follows: Machine-men, \$6, with \$6.50 for shaft work; timbermen, \$6; timbermen helpers, \$5.50; shovelers and trammers, \$5.50; top-men, \$5.50; hoisting-engineers, \$6.50; boss carpenter, \$7.50; carpenters, \$7; head blacksmiths, \$7; blacksmith helpers, \$5.50; tool-sharpeners, \$6.50; lathe-men, \$7; machinists, \$6.50; machinist helpers, \$5.50; electricians, \$6.50.

LIDA.—Eighteen inches of ore assaying \$145 in silver, lead, and copper has been opened on the foot-wall of the

vein at a depth of 225 ft. in the Allied, in the new district of that name, which was formerly known as the Indian Gardens. The find was made in a drift driven west to cut the downward extension of the ore-shoot. Tests of the ore are being made and it is planned to erect a 50-ton concentrator. There is estimated to be 10,000 tons of material of mill-grade exposed.

DIVIDE.—Ore from the Treasure Divide lease on the Revert is being shipped to the MacNamara mill at Tonopah. The material is being mined at and near the bottom of a 100-ft. shaft in which a 10-in. seam assaying from \$5000 to \$15,000 has been exposed from the 70-ft. point. Machinery for use in sinking the shaft to greater depth has been purchased.

BEOWAWE.—J. K. Turner, a mining engineer of Goldfield, is examining the Cortez mine, 26 miles south of

from the present depth of 30 ft. Lateral work will be done from the winze and the entire surface of the west-dipping shale will be prospected in this vicinity before sinking of the shaft is resumed. Assays of from \$5 to \$7 are being secured. A raise has been started from near the face of the east cross-cut on the 375-ft. level of the Great Bend. The face of the cross-cut is now vertically under the main east-raking ore shoot on the upper levels and it will be extended to open the western edge of those shoots.

UTAH

STRIKE AT BINGHAM INSTIGATED BY I. W. W. OPERATIONS AT ALTA AND PARK CITY.

BINGHAM.—On the morning of February 9, all of the mines in this district received letters signed by the

GOLD HILL, IN THE DEEP CREEK DISTRICT, UTAH

here, for Coleman and Reitze, New York brokers who recently took over the Candelaria mines on an option and sold them on a report made by Mr. Turner. It is reported that the brokers have the same object in view in having the Cortez examined. They have secured an option from the Wenban estate. The Cortez owns 48 claims, developed through tunnels reaching a maximum depth of 1500 ft. on the vein, with miles of other workings. According to Mr. Turner, the Cortez produced \$12,000,000 in silver ore during the 'seventies. The mill tailing is being sampled by F. C. Beedle, who successfully re-treated the tailing from the old mill at Belleville. The Cortez is in Lander county.

GOLD MOUNTAIN.—Work in the drift tunnel of the Washington gold-quartz mine has been discontinued because of an unusually hard formation found on both walls of the vein, and another tunnel, now 40 ft. long, is being driven in a cross-vein that was the main objective of the first. This cross-vein has been prospected with shallow shafts and trenches and assays of as high as \$150 in gold, silver, and lead have been secured. The face of the tunnel assays \$10, with a 10-in. seam assaying \$81.50. The main ore-shoot is estimated to be 75 to 100 ft. from the present face.

GOLDFIELD.—An air-power hoist has been erected at the winze being sunk from the 815-ft. level of the Grandma and the winze will be continued to at least 100 ft.

'Grievance Committee' of the Metal Mines Industrial Workers Union No. 88, an auxiliary of the 'I. W. W.', making the following demands on the mining companies:

1. Eight-hour day, collar to collar.
2. Two men on all machines.
3. Minimum wage of \$6 per day for men working underground.
4. No tools to be carried on cages when lowering or hoisting men.
5. Modern change-houses to be installed immediately.
6. No man to work alone.

The mining companies were given 24 hours in which to comply with these demands. No attention was paid to them by any of the companies. For two weeks prior to the date when the letters were received, there had been rumors that members of the I. W. W. were contemplating making demands, but little or no credence was given them. Recently the underground mines in this district have had a total of about 1200 men on the payroll and a similar number were engaged in surface operations at the Utah Copper and other properties. On the morning of February 10, about 500 metal miners, members of the I. W. W., went on strike. The United States mine was forced to suspend operations, while about one-fourth of the day shift of underground men at the Utah Apex reported for work. All of the mill, carpenter, and mechanical forces of the Apex reported for work. At the

Utah Consolidated (Highland Boy) mine, about 10% of the underground men failed to report. The following day the situation was more serious; less than 10% of the miners at the Highland Boy mine reporting, while the Utah Apex had but a small force, sufficient to keep the pumps running. The United States and Utah Metal & Tunnel companies were closed completely. On the afternoon of the 10th, Albert Wills, said to be an alien, born in Wales, and one of the leaders of the I. W. W. in the Western country, was arrested on a Government charge and taken to the county jail in Salt Lake City. None of the employees of the Utah Copper Co. quit work as a result of the strike, and operations at that mine are going along in a normal manner. Twenty-six special deputies, and a number of regular deputies, were sent to Bingham and stationed at the various railroad bridges and tunnels to guard against their being tampered with by strikers. About a half-dozen strikers were arrested the first day of the strike on the charge of intimidating the employees who wished to remain at work. At present machine-men in the mines here receive \$5 per day of 8 hours and muckers \$4.50. Operators state that in view of the present program of curtailment, they cannot afford any increase in wages, as a number of the properties are just about 'breaking even'. Several hundred of the strikers have already left camp. The present strike is the first labor trouble of any importance since the general strike in September 1912, which lasted for nearly three weeks and involved every mine in the camp. On February 12, handbills were distributed calling on employees of the Utah Copper Co. to strike, but these met with no response.

PARK CITY.—Shipments of ore for the week ending February 7 totaled 2382 tons, as compared with 2324 tons for the previous week. Of this amount, Judge Mining & Smelting shipped 802 tons; Silver King Coalition, 542 tons; Ontario, 664 tons; Daly-West, 209 tons; Naildriver, 110 tons; and Daly Mining, 55 tons.

Preparations are being made to take ore from the various workings in the Naildriver mine through the old Queen tunnel. This arrangement will eliminate a half-mile haul over heavy roads, and will permit increased shipments from this property. Ore-bins are being constructed at the portal of the Queen tunnel. At present from 20 to 30 tons per day is being mined. In the south cross-cut from the 600-ft. level, four feet of shipping-ore was recently opened up. This ore apparently lies in a fissure which parallels the one from which considerable ore has been and is being mined. The same orebody has been cut, it is said, in the south cross-cut on the 700-ft. level.

ALTA.—Assays of ore taken from the rich shoot recently opened up in the drift along the 125-ft. level in the Sells mine, adjoining the South Hecla, show high results, according to W. H. Weyher, general manager. An average sample of the face, which is approximately four feet wide, assayed \$13.20 in gold, 157.2 oz. silver, 6.9% lead, and 11.29% copper. With the drifting done along the foot wall of the vein and with the drilling already done, an orebody 8 ft. long, 10 ft. high, and 8 ft.

wide from the foot-wall of the vein toward the hanging-wall side, has been proved. In a cross-cut, run approximately 15 to 20 ft. back from the face, the fissure is 18 ft. wide.

No shipments are being made from the Cardiff mine at present, but mining is being conducted regularly and the ore stored in the large bins about three miles below the mine and on the main Big Cottonwood highway. Officials of the company report the mine in excellent condition and recent developments have been highly gratifying. As soon as the roads permit, a very large tonnage will be available for immediate shipment.

WISCONSIN

REVIEW OF ZINC AND LEAD MINING DURING JANUARY.

With prices for zinc ore again fairly well established and demand for all grades exceptionally good, operators began the new year with an increased production of ore. All of the large operating groups started new drilling-machines, and virgin ground, held under lease, was explored. Noteworthy strikes were made at several points in the field and by the middle of January the zinc-mining industry of south-west Wisconsin wore a more cheerful aspect than at any time since the close of the War. Premium-grade blende, offered by operators of electromagnetic separating-plants, commanded a base price of \$61 per ton, 60% standard commercial assays, with the top grades bringing as high as \$63 per ton. This base held until well along into the third week when a decided slump in price occurred, the base receding to \$55 per ton for premium blende or first grades of zinc ore, and an even lower figure was quoted for prime Western blende, or second-grade zinc ore. The drop was explained by the fact that two of the leading consumers had encountered fresh labor troubles at smelters, temporarily stopping their purchases. This enabled their weaker competitors to adjust the markets to suit themselves. Another factor is to be found in the lowering of sterling exchange, which reached a point under \$3.50, practically stopping slab-zinc exportations. Slab zinc dropped from 9.5c. per pound to less than 9c., East St. Louis, and with the drop in the price of metal came a corresponding lowering in the level of zinc-ore prices. Some of the ground lost was recovered before the close of January, the base at the end of the month reaching \$57 per ton on first grades and \$55 per ton on second grades.

The rapid shift in prices affected both production and shipments. Low-grade producers, many of whom had discontinued and who had but recently resumed operations under the incentive of advancing prices, were the first to feel the effects of lower markets and recoveries at mills of run-of-mine ore decreased. Shippers of the high-grade refinery-ore observed caution in marketing their product, because they felt that the prices obtained for metal warranted better offerings for zinc ore, and there was a well defined disposition to hold high-grade blende for better prices.

Producers of lead ore enjoyed a good month and prices were steady and high. The base price held almost uni-

formly throughout the month, at \$100 per ton, base 80% metallic content. Buyers engaged in the field were anxious enough to submit bids, but sellers wanted a base of \$110 per ton, and were content to hold finished lead-ore concentrate. Lead ore in reality is becoming scarce and higher prices may be anticipated. Mining companies able to confine operations to lead-ore recovery have done so, and have made some money. The present winter has been one of the severest known to the field in thirty years. Heavy snows and extremely low temperatures have hindered operations everywhere. The coming spring will find small companies seeking lead ore in top runs and shallow surface-diggings, should present prices for lead be maintained.

There were no shipments of iron pyrite during the month of January. Prices have been unsatisfactory for a long time and zinc-ore separating-plants have been piling up the ore recovered and the surplus on hand is now the largest ever known in Platteville and the surrounding districts of the Wisconsin field.

Shippers of carbonate-zinc ore have been marketing conservatively, although the price offerings have been fair. The price for the greater part of the month ranged from \$30 to \$35 per ton, but in the closing days of the month an advance was made to \$38 when the shippers strangely withdrew entirely, possibly in anticipation of still further advances.

Deliveries of both zinc ore and lead ore during January were as here shown:

Districts	Zinc, lb.	Lead, lb.
Benton	11,982,000	464,000
Livingston	6,020,000
Galena	4,492,000	362,000
Hazel Green	1,596,000
Cuba City	1,370,000	312,000
Highland	720,000
Linden	628,000	32,000
Platteville	460,000	160,000
Shullsburg	60,000
Total	27,328,000	1,330,000

Deliveries of high-grade blende from refineries were made to smelters during January as follows:

Company	Blende, lb.
Mineral Point Zinc Co.	4,896,000
National Ore Separators	3,816,000
Wisconsin Zinc Co.	3,792,000
Block-House Mining Co.	460,000
Total	12,958,000

The gross recovery of milled ore for the month amounted to 13,737 tons. Of this the Mineral Point Zinc Co. received 4456 tons; National Ore Separators, 4000 tons; Skinner Roasters, 3471 tons; and the bulk of the remainder was shipped from mines to smelters direct. Of the high-grade the Mineral Point Zinc Co., received 2448 tons; American Zinc Co., 1896 tons; Grasselli Chemical Co., 1346 tons; United Zinc Smelters, 1033 tons; Illinois Zinc Co., 640 tons; Lanyon Zinc Co., 202 tons. The total net deliveries out of the field, for the month, to smelters, amounted to 7904 tons.

BRITISH COLUMBIA

PLANS FOR RECOVERING PLATINUM ON CARIBOO RIVER.

ATLIN.—While British Columbia has been comparatively free from troubles with respect to its placer-mining camps, disputes sometimes arise. One of these has been before the courts for some months. The disputants are Isaac Matthews and L. Schultz, the former being the owner of the Poker placer-gold claim on Spruce creek in the Atlin district and the latter the owner of an adjoining claim known as the Peterboro. Mr. Schultz, in the course of operation, permitted his men to encroach be-

A BIT OF BRITISH COLUMBIA

yond what Mr. Matthews considered his line. In the action that followed Mr. Matthews was upheld, whereupon he followed up his success with a suit for damages to the extent of \$100,000. This latter litigation is about to come to trial and developments are being very closely followed by the placer miners.

BARKERVILLE.—J. M. Yorston reports that development work is proceeding on the Prosperpine Mountain properties. Mr. Yorston also states that some excitement was occasioned recently by the discovery of quartz-gold in the creek about three miles from Barkerville. Much is expected both by miners and settlers from the Pacific Great Eastern railway, now being constructed through the Cariboo into the Peace River country. This new railroad will open up a country rich in mineral resources.

The plans of the Cariboo Gold-Platinum Extracting Co., Ltd., are attracting interest. The company's prop-

erty, situated about 20 miles east of Quesnel, consists of five lenses on the river and a ranch of some size, the latter having been acquired recently. Machinery now is being transported over the Cariboo road, consisting of a drag-line excavator with a Shearer & Mayer one-yard bucket, a specially designed concentrator with a capacity of from 25 to 150 tons of black sand per day, and a steam plant. G. J. Marsh, president and general manager of the company, states that he has been successful, after twenty-five years of experiment, in the extraction, at a reasonable cost, of gold and platinum from the black sand. In describing his method he asserts that the sand first is crushed to pass a 200-mesh screen and afterward treated by an electro-chemical process. Tests, Mr. Marsh declares, have proved its commercial feasibility. The importance of this to British Columbia is emphasized by the many creeks, rivers, and beaches where deposits of black sand are to be found. In dredging and other placer operations black sand is the source of much trouble on account of its high specific gravity making it impossible to recover gold and platinum at a profit. Mr. Marsh appears to be confident that success is assured for his company. Before operations start about \$250,000 will have been invested, and the capital, it is said, has been raised in Minneapolis. To induce individual miners to produce black-sand concentrate for treatment at the extraction plant Mr. Marsh has a portable concentrator which he proposes distributing by sale or lease, and he hopes to see the bars of the Fraser and other rivers exploited.

KASLO.—The Utica mine, on Paddy's peak, is attracting much attention in this district. A portion of the mine workings was leased to A. J. Poyntz, formerly superintendent of the property, and shortly afterward he made a strike of such richness that the returns approximated \$100,000. His lease is to expire in the course of two months and it is expected that C. F. Caldwell, one of those interested, will take steps to interest capital in the further development of the property. The ore taken out by Mr. Poyntz was rich in silver.

ONTARIO

COBALT.—DECISION REGARDING ASSESSMENT WORK.

COBALT.—The silver mines of Cobalt are benefiting from the high rate of exchange between the United States and Canada. On the date of writing, with silver quoted at \$134½ per ounce in New York, and with American funds at a premium of 18c., the Canadian producers are receiving \$1.59 per ounce for their silver.

At the leading mines, including the Nipissing, Kerr Lake, and Coniagas, the cost of producing silver averages about 43c. per ounce. The camp as a whole produces its silver at an estimated cost of 58c. per ounce, the cost at some of the smaller mines being more than 80 cents.

The Mining Corporation of Canada has decided to carry on a limited amount of exploration work in Butt township, in the district of Nipissing, the work to be started in the early spring. Late last summer the discovery of radium-bearing ore attracted attention to that district, which is likely to be the scene of extensive pros-

pecting operations during the coming summer season.

On February 2 the Coniagas company paid \$100,000 in cash for the Trethewey-Cobalt mine. The Coniagas also has an option on the Gamble-Thompson claims in the Gowganda district.

The system of representation of employees is working satisfactorily at Cobalt. One of the first moves has been the adoption of a 'Sick Benefit Fund' by the Dominion Reduction company. The plan is regarded with favor throughout the town and is expected to be adopted by other companies.

The Kerr Lake has commenced the year with production at the rate of 1,250,000 oz. per year. Costs for the past fiscal year were 40.81c. per ounce. Allowing for increased costs to around 45c. on account of the high bonus paid to the employees, it is still possible that net profits may this year approximate \$1. On the indicated production this would amount to \$2 per share on the company's 600,000 issued shares.

TORONTO.—A decision of considerable importance to mining men has been rendered by the Mining Commissioner in relation to the ownership of a claim in Bernhardt township in the Kirkland Lake district. The claim was originally held by Robert Ferguson, but was restaked on behalf of A. Koury on the ground that Ferguson had not performed the requisite assessment work. It was proved that Ferguson had hired men to do the work, paying them upward of \$200, and that they had made a sworn statement as to having done so. But the Commissioner decided against him and awarded the claim to Koury. The decision has caused much adverse comment as likely, if sustained, to work much hardship to claimholders who are dependent on men employed to do their assessment work in their absence, and the fear is expressed that it may deter outsiders from investing in undeveloped prospects.

The influx of American capital into the mining districts of Northern Ontario is being increased by the present high rate of United States exchange. With American money at its present premium in Canada, the purchaser saves about \$18,000 on every \$100,000 in comparison with the Canadian buyer, and in addition secures the premium in marketing the output in the United States. There is every prospect that investments in the newer gold and silver camps will show an increase.

A large number of Canadian silver-mining companies are desirous of resuming the trade in cobalt-oxide with Germany, which had assumed considerable proportions before the War. The depreciation of the German mark presents an obstacle, and inquiries which have been made as to whether business could be done under a system of government credits, point to the conclusion that this is hardly feasible as public opinion would be strongly against it. The suggestion has been made that the trade should be carried on by barter, the companies exchanging cobalt-oxide for pottery, in the manufacture of which cobalt-oxide is extensively used. M. J. O'Brien, a prominent Cobalt mine owner, is expected to visit England shortly in connection with the matter.

CALIFORNIA

The following awards have been made by the War Minerals Relief Commission to California claimants who operated chrome-properties during the War:

G. F. Finlister, Patterson, \$3246; Mortimer Savage, Forest Hill, \$4905; Samuel H. Dolbear, San Francisco, property in Siskiyou county, \$10,955; J. S. Shields, East Auburn, \$317; John Anderson, Altaville, \$708; C. E. Shaffer and Frank Atherton, Jamestown, \$470; Geo. E. Brown, Roseville, \$223; Herman Costello, Nevada City, \$157; R. H. Lake, Yreka, \$516; N. E. and E. E. Hayes, Fort Jones, \$198; I. B. Sovy, Etna Mills, \$167; Chastain Brothers, Gazelle, \$1034; N. Lambert, Fort Jones, \$385; W. C. Green, Georgetown, \$555; D. F. Wiley, Folsom, \$605.

Reports reaching the Western mining districts that the Minerals Relief Commission is considering payment of claims filed by claimants who operated without formal requests from the Government are erroneous. The Commission has no such power, as the law under which present awards are made specifically states that only those claims may be considered where a formal request can be shown.

The Committee on Mines of the two houses of Congress is, however, considering amendments to the present law which would permit compensating those who operated in good faith, accepting as sufficient notice the appeal made by the Government through newspapers and placards.

Auburn.—Work has been resumed at the Voss mine, in the Pilot Hill district, and the erection of a 40-stamp mill is proceeding. This property was formerly a noted gold producer and is said to contain large reserves of profitable ore. San Francisco and Idaho people are chiefly interested.

Grass Valley.—The Alcalde company has completed repairs to its shaft and resumed development on a lower level. The mill will start before the end of March. The Empire Mines Co. has practically completed the electric railway from the Pennsylvania mine to the Empire mill. The installation of 20 stamps in the Empire mill has been completed, bringing the total to 60. Classifying equipment for the new battery is being placed in position.

Ingot.—The Afterthought Copper Co. has purchased from Chester Lowman the Donkey copper property. The Donkey has been developed sufficiently to establish the existence of good ore. It was worked for several years by the late Alexander J. Cook, who was the original locator.

Nevada City.—Preparations have been made for the resumption of work at the Delhi group, near Columbia hill, under the management of Harry B. Skewes. The long cross-cut from the shaft is to be extended to the vein. The property is under bond to A. A. Codd of Reno.

IDAHO

Coeur d'Alene.—The Caledonia Mining Co. had a surplus of \$570,520 on December 31 last, according to the annual report, just issued from its office at Kellogg. This is nearly 22c. per share on the issue of 2,605,000 shares. The statement of production and operating cost shows the production of 15,225 tons of ore in 1919. This ore yielded 4,224,053 lb. of lead worth \$231,210; 507,862 oz. of silver worth \$548,824; and 56,000 lb. of copper worth \$5179, a total of

\$785,213. The net value of the bullion was \$558,421 after a deduction of \$226,791 for smelter charges. The average content of the ore was nearly 14% lead and over 33 oz. of silver to the ton, according to assays.

George Decker, president of the New Caledonia Mining Co., which is the outgrowth of the consolidation of the Bernice and Wardner companies of the Kellogg district, has been in Spokane to purchase new machinery. Ore has been followed for 100 ft. in a drift run on the 750-ft. level in the property of the Ajax Mining Co., according to report from A. C. Bixby, manager. The drift is proceeding with two shifts and at the rate of eight feet per day.

Four hundred miners in the employ of the Federal Mining & Smelting Co. at its Morning mine here averaged nearly \$8 per day in wages for January, according to the records of the company.

The men are employed under a contract system whereby they receive a fixed price per ton for all ore mined and delivered to the mill. They furnish the labor only, everything else incident to the extraction of the ore being supplied by the company. No limit is placed by the company on the tonnage that may be produced.

Besides miners, the contract system includes the shift-bosses, motormen, cagers, pipemen and timbermen, who receive a bonus of 50c. per day on top of their contract wages. The average wages received for the second half of January follow: motormen, cagers, pipemen, \$7.93; men on 1400-ft. level, \$7.86; men on 1800-ft. level, \$7.94; and men on 2000-ft. level, \$7.83.

Lemhi County.—Development of the property of the Sunset Mining Co. has reached the point where full tonnage at the mill can be maintained, according to G. W. Wood, manager for the company. The mill is of 50-ton capacity and is being operated 24 hours per day.

NEVADA

Mina.—The shaft of the Fagan-Consolidated is now down 71 ft. and the lessees' shaft has been sunk to a depth of 36 ft. The vein in the south-west drift of the Fagan-Consolidated has widened and some galena has been found.

Pioche.—Ore-shipments were increased last week to a total of 2800 tons as compared with 1950 tons the week before. The increase was due to the shipments from the Prince Consolidated mine which doubled its output, shipping 1700 tons of ore last week.

The shipments were as follows:

Prince Consolidated, 1700 tons; Virginia Louise, 650; Black Metals, 150; Combined Metals, 100; Consolidated Nevada-Utah, 100; Pioche assay office, 100; total, 2800 tons.

OKLAHOMA

Miami.—A committee of the Chamber of Commerce of Miami will officially present the State with a deed to 40 acres of land near the city as a site for a State School of Mines. This will complete the matter so far as the question of placing the school at Miami is concerned, as the State has agreed to proceed at once with the construction as soon as the deed is in its possession. Plans for the buildings are under way. The legislature appropriated \$200,000 for buildings, and the appropriation will be increased as requirements demand.

STATEMENT BY MR. HOOVER

On February 11 Herbert Hoover made public the following letter to his friend, Casper W. Hodgson, of Yonkers, New York:

I have noted your feeling that I should answer some of the solemn discourses on my private life and crimes. I do seem to get into the way of politically-minded folks even when trying to keep out of politics.

Some things that have been said of me cause me a sense of financial oversight. For instance, I have made careful inquiries and I regret that so far I cannot find:

(A) The \$10,000,000 I am said to have made in my early youth or even middle age, or altogether, or any respectable part of it.

(B) The investments I am supposed to have in Great Britain.

Like the negro porter who was asked to change \$10, I am grateful for the compliment. I am sorry that these sums do not exist, for they would be useful for the Children's Relief.

I have also given deep consideration to the other items mentioned:

(A) Am I a British subject? Did I ever apply for such citizenship? No. Many generations of persecuted Quaker ancestors would rise in their grave at such a discovery. They should remain quieted, however, for no Californian could live three months in a London climate and become a British citizen if he knew it. One thing that reassures me that this did not happen without my knowledge is that the British refused to allow me to come into their island during the War without an American passport. Also, I feel that my accent was disinfected of any English, French, Chinese, Russian, or other taints, by my presence in the United States a portion of every calendar year of my life—except three—even including the five in which that United States exercised its right to draft my services, a good portion abroad.

(B) Did I ever rent a 'residence' abroad? I plead guilty of this crime, but in mitigation I do appeal to the feelings of fathers who object to hotel life for babies and children.

(C) What about that political lunch where I was supposed to have entered upon a dreadful conspiracy against the wealth of the American people? My real distress in this matter is not to prove an alibi or even to complain that my name was not even mentioned, as the guests assert, but it is that I was not even invited and therefore lost an excellent lunch.

(D) I plead guilty to the criminal charge of pursuing my engineering profession in foreign parts again and again. I have a fervent hope that this new doctrine of criminality will not deter our citizens from extending American professions and business anywhere in the world. They always bring something home, and pay taxes on it.

(E) I gather also that it is moral turpitude on my part to have managed large enterprises. The hope to rise from the ranks of labor to the ranks of management will, however, probably not be crushed from the hearts of the American boy even by this onslaught.

Announcement that there will be no general extension of time for the filing of income-tax returns has been made by the Bureau of Internal Revenue. Complete returns, accompanied by at least one-fourth of the amount of tax due, must be in the hands of collectors on or before March 15, 1920. The only extensions to be granted, it is announced, are those in specific cases where urgent need for additional time in preparing the return is conclusively shown. To avoid penalty every person whose income for the calendar year equaled or exceeded \$1000 or \$2000, according to their marital status or their status as the head of a family, must file a return. The law makes no exceptions, the penalty for failure being a fine of not more than \$1000.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

E. P. Earle is at Pasadena.

L. D. Ricketts is at Chandler, Arizona.

Newton B. Knox has returned to London from Spain.

E. A. Weinberg, formerly in Queensland, Australia, is now in New York.

J. D. Millen has resigned as manager of the Mount Bischoff tin mine, Tasmania.

F. V. Bodfish, manager for the Alta Tunnel & Transportation Co., at Alta, Utah, is in New York.

H. L. Sulman has been awarded the gold medal of the Institution of Mining & Metallurgy, London.

E. P. Mathewson did not come to San Francisco, but proceeded direct from Vancouver to New York.

C. H. Macnutt is now manager for the Black Lake Asbestos & Chrome Co. at Black Lake, in Quebec.

L. S. Cates has returned to Salt Lake City after a trip to the Ray Consolidated properties in Arizona.

Morton Webber was here during the week; he has gone to Pasadena, on his way back to Salt Lake City.

C. M. Eye has gone to Humboldt and Hayden, in Arizona, and expects to come to San Francisco on his return.

Carl J. Trauerman, mining engineer of Butte, Montana, is in New York, and can be reached at A. J. M. E. headquarters.

W. H. Goodchild has been awarded the Consolidated Gold Fields gold medal by the Institution of Mining & Metallurgy, London.

Ben. B. Thayer, vice-president of the Anaconda Copper Mining Co., has gone to South America to inspect the Andes copper mines, in Chile.

G. L. Johnson, connected with the Chile Copper Co. at Chuquicamata, Chile, was in Utah recently, visiting mining and metallurgical plants.

Cecil H. Desch has been appointed Professor of Metallurgy in the University of Sheffield in succession of J. Oliver Arnold, who resigned recently.

George R. Allen, president of the Chosen Minerals Co., who arrived on 'Shinyo Maru', has gone to New York. He expects to return to Korea early in May.

Ray B. Earling has resigned his position as superintendent of the Metcalf division of the Arizona Copper Co. to accept a position with the U. S. S. R. & M. Co. at 55 Congress Street, Boston.

D. C. Jackling received the Distinguished Service Medal at the hands of General Liggett at the Presidio on February 10. The medal was bestowed for his valuable services as organizer of Government explosive plants.

Donald Fraser, who, with his brother, William Fraser, organized the Pahang Corporation, one of the first organizations to exploit the tin deposits of the Malay peninsula, is visiting mining properties in Utah and Idaho. He is associated now with W. E. Reuss in the development of the Elmore Copper Co., which has large holdings near Mountain Home, Idaho.

David Swickheimer died at Denver, Colorado, on February 5. He was born in Ohio and was 67 years of age. He located and opened up the Enterprise mine, on Newman hill, at Rico, Colorado, and made a fortune by selling it to Crawford & Posey, who formed the Enterprise Mining Co. He had a reputation for honesty and integrity in all his dealings.

THE METAL MARKET

METAL PRICES

San Francisco, February 17

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	12.00
Copper, electrolytic, cents per pound.....	19.00
Lead, pig, cents per pound.....	9.00—10.00

Spelter, cents per pound.....	10.00
Zinc-dust, cents per pound.....	12.50—15.00

EASTERN METAL MARKET

(By wire from New York)

February 16.—Copper is dull but steady. Lead is quiet and strong. Zinc is inactive and firmer.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (sterling fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

"American iron and steel mills will not even be slowed down on account of foreign exchange—at least not for any length of time, and then only in event of developments highly improbable—so long as there are cars and locomotives to haul raw materials and finished products," says a leading independent manufacturer. "It is the railroad situation, not foreign exchange, that is the neck of the bottle for the steel industry. The railroad situation, owing to the constantly decreasing supply of equipment and locomotive power, is serious at present, but likely to be corrected to an extent in the near future with the impending return of the properties to private owners."

"The public seems to forget that on an average only 10% of American iron and steel products are exported. The past year the proportion may have been a little larger owing to the fact that pre-regulation talk had a depressing effect on domestic buying for a considerable period and foreign consumers took advantage of that situation to supply pressing needs. That exports of iron and steel were heavier than usual in 1919 merely accentuates the fact that to such extent home demands had to suffer, as there is the same unsatisfied steel need here as in most foreign countries which have been buying more than ordinarily."

"It would be useless to say that were foreign exchange to remain in its present precarious state indefinitely, thereby affecting adversely our other foreign trade, the steel industry could escape even though only indirectly affected. There is no probability, however, that exchange will permanently remain so low. It is simply another case of the 'darkest hour just before the dawn.' Corrective measures will be applied. Europe is slowly awakening to the fact that she will have to go to work or give collateral for what she gets from this country. Natural wealth of even the war-driven countries, such as their farms, forests, and mines, is still unimpaired. They only need application of man-power to renew the golden stream that will mean prosperity to them and, in added measure, to the whole world. Europe has been awaiting payment of indemnities and the help of America before she has tried to help herself. In a measure the affected people are awakening from some of their delusions. As this occurs, the beginning of the end of the trouble now being experienced here and abroad will in all probability commence at once."

Steel manufacturers generally point to the fact that there are no surplus supplies of steel at mills—further that the output which has been temporarily damaged back by inadequate rail facilities—in jobbers', retailers', or consumers' hands. Deferred requirements are vast in the case of the railroads, months ago it was estimated to amount in the aggregate to approximately 10,000,000 tons.

Interruption to output would only make the situation so much more acute, stimulating the soaring prices that pressure of demand is occasioning. A year ago the Railroad Administration refused to buy needed steel even though manufacturers made price concessions. The result is that the country is being treated to the spectacle of a revival of war-commanding powers to get a small fraction of the steel tonnage needed for railroads for current replacement and upkeep.

Eastern Metal Market

New York, February 11.

Buying of most of the metals has been light and prices of some have declined. The value of foreign exchange which fell to record low levels is a predominating influence in prices and in buying.

Copper demand is light and prices have eased slightly.

Tin has declined several cents because of the erratic change in the pound sterling.

The lead market is the strongest of all but demand is not heavy. Prices are unchanged.

Values of zinc have eased off because of the foreign-exchange situation and because of light demand here.

Antimony is fairly active and higher.

IRON AND STEEL

Because of increased obstacles to production during the last week, including besides shortage of cars, railroad embargoes, and a threatened railroad strike, steel output is not more than 80% of capacity. Insistent buying of both pig-iron and steel augments the upward tendency in prices which are now almost anything. In finished steel, business is being done at \$5, \$10, and over \$25 per ton above the March 21, 1919, schedule, so much talked about, and to which the Steel Corporation still adheres. The independent steel makers, following their practice of committing themselves not much over three months, have been taking business at about their current capacity, while the United States Steel Corporation's statement of unfilled tonnage for January indicates a booking rate fully 50% above capacity, with orders now in sufficient volume to carry to December. Following two weeks of heavy buying in the East, pig-iron transactions have been less active.

COPPER

Demand has fallen off and prices have eased slightly. Under present conditions it is natural that consumers should be backward about committing themselves, and in addition to this it must be recognized that most of the heavy buyers are well covered for at least the fourth quarter. Most large producers are quoting electrolytic at 19c. and Lake copper at 19.25c., New York, for early delivery, with second quarter 1c. above these figures. With the present condition of foreign exchange any export business seems out of the question and is not being considered. There is an outside market in which it is stated electrolytic copper can be bought in lots of carloads up to about 500 tons, at around 18.75c., New York, but the quantity is not believed to be heavy.

TIN

The remarkably low levels to which the British pound sterling fell in the last week of course dragged down with it prices of tin for both spot and future shipment. On February 4, the day of lowest values, spot Straits sold as low as 56.75c., New York, and it is estimated that about 500 tons was disposed of. Buying in general has been very light. Yesterday spot Straits was quoted at 58.25c., New York, values having stiffened each day since the low level on February 4. In future shipment very little business is possible owing to the difficulty in gauging future value of the pound. On Monday, February 9, some light business was done at around 59c. early in the day for February-March shipment, with as high as 59.75c. asked late the same day. The London market has advanced again, spot Straits being quoted yesterday at £335 10s. against £386 5s. per ton a week ago. Arrivals thus far this month have been 650 tons, of which 150 tons has come in at Pacific ports. The quantity of tin affoot is returned as 7150 tons.

LEAD

This market is probably the strongest of any of the major non-ferrous metals. On Saturday, February 7, the American Smelting & Refining Co. advanced its price 4c. per lb. to 8.75c., New York, or 8.50c., St. Louis, bringing it on a par with the outside market which has ruled at this level in New York for some time. Demand is fair and prices are regarded as strong. Spot lead is regarded by some as unobtainable at less than 9c., New York, being scarce in this locality. While production has improved it has not been as fast as was hoped for and, in the view of some, consumption is heavier than the rate of output.

ZINC

This market has been somewhat like that of tin because of the exchange situation which has been a big factor in zinc for some weeks. Values have fallen sympathetically with those of the pound sterling but not as drastically as in tin. Foreign business is of course not feasible but inquiry from galvanizers in this country has been decidedly better in the last day or so. This has tended to stiffen values a little and this tendency has been aided by foreign exchange. Prime Western for early or first-quarter delivery, after falling to around 8.55c., St. Louis, or 8.90c., New York, is now quoted at about 8.65c., St. Louis, or 9c., New York. For second quarter values seem to be about 8.50c., St. Louis, or 8.85c., New York, though some producers will not sell at less than 8.65 to 8.70c., St. Louis, for that position.

ANTIMONY

Demand is very good and the market is strong. Wholesale lots for early delivery are quoted at 11.50c., New York, duty paid.

ALUMINUM

Virgin metal, 98 to 99% pure, is unchanged in a quiet nominal market at 31.50c. and 32.50c., New York, in wholesale lots for early delivery.

ORES

Tungsten: The market is lifeless and marking time pending some tariff decision. Quotations are nominal at about \$6.50 per unit for Chinese ore, \$10 for Bolivian, and \$15 for American high-grade. Ferro-tungsten is nominal at around \$1 per lb. of contained tungsten.

Molybdenum: Quotations are nominal at 75c. per lb. of MoS₂ in regular concentrates. A number of actual transactions can be reported for the first time after a long interval of virtually no trading.

Manganese: High-grade Indian and Chilean ores are offered at \$1 per unit against 80c. realized about two weeks ago and 50c. two months ago. Imports in December are returned as 36,376 tons, bringing the 1919 total to 332,344 tons which compares with 491,308 tons for 1918.

Manganese-Iron Alloys: The ferro-manganese market is strong but not particularly active. Domestic producers are quoting second half at \$160, delivered, and outside of a few lots of spot alloy, very little seems available for first half. Spot delivery has sold at \$175, delivered, this week. About the only British alloy available is for second half for which \$152 to \$155 is asked and also offered. Spiegeleisen is strong at \$55 to \$57.50, furnace. Production of ferro-manganese in January was 18,062 gross tons against 11,210 tons in December, according to blast-furnace reports of "The Iron Age". The spiegeleisen output was 5895 tons in January as compared with a production of 4528 tons in December.

Company Reports

SUPERIOR & BOSTON COPPER CO.

Report for the year ending September 30, 1919.

Property: mines in the Globe district, Gila county, Arizona.

Operating Official: E. G. Deane, manager.

Financial Statement: revenue for the year was \$24,327; expense \$39,190; deficit \$14,862.

Dividends: none to date.

Development: 4589 ft. of development work was done during the year largely directed toward determining ore-bodies in the Great Eastern and Old Dominion veins.

Production: 773 tons of 3.86% copper ore was shipped on company account and lessees shipped ore returning royalties amounting to \$4366.

CONIAGAS MINES, LTD.

Report for the year ending October 31, 1919.

Property: mine, stamp-mill, and cyanide plant at Cobalt, Ontario, and smelter at Thorold, Ontario.

Operating Officials: R. W. Leonard, general manager; F. D. Reid, manager; E. H. Clemens, mine superintendent.

Financial Statement: sales of ore and smelter products totaled \$3,574,456. Operating profit, \$645,352.

Dividends: four dividends, No. 43, 44, 45, and 46 totaled \$400,000, making total to date \$9,640,000.

Development: a large quantity of low-grade milling-ore with occasional 'patches' of high-grade has been opened up during the year; 1634 ft. of development work was done.

Operations: mill operated continuously treating 71,743 tons of ore averaging 3.38 tons per stamp; 322 tons of high-grade concentrate averaging 2067 oz. of silver per ton was shipped.

CHILE COPPER COMPANY

Report for quarter ending September 30, 1919.

Property: owns the stock of the Chile Exploration Co., which owns copper mines and reduction plants at Chuquibambilla, Chile.

Operating Officials: H. C. Bellinger, general manager; E. E. Barker, mine superintendent.

Financial Statement: net profit on copper delivered, \$773,945, as compared with \$214,139 for second quarter. Profit after paying bond interest, \$45,114, as compared with loss of \$513,597 for second quarter.

Dividends: none.

Operations: 828,914 tons mined and leached, averaging 1.69% copper.

Production: 23,583,722 lb. copper was marketed with an average realization of 18.866c. per pound.

NEVADA CONSOLIDATED COPPER COMPANY

Report for quarter ending September 30, 1919.

Property: mines at Ruth, Nevada; mill and concentrator at McGill, Nevada; the Steptoe smelter. The company also owns controlling interest in the Nevada Northern railway.

Operating Officials: C. B. Lakenan, general manager; Robert Marsh, Jr., mine superintendent; George C. Riser, mill superintendent; R. E. H. Pomeroy, smelter superintendent.

Financial Statement: operating profit for the quarter, amounting to \$331,153, reduced the accumulated losses for the year to \$394,986. Profits did not equal dividend disbursements, however, so that there is a net deficit of \$1,711,321 for the first nine months of 1919.

Dividends: dividend in third quarter of 1919, \$749,796. Total to date \$44,519,225.

Production: 454,255 tons averaging 1.54% copper were

treated; 73% was from the open pit, 27% from Ruth underground workings. Cost per pound of copper was 21.68c. as compared with 16.85c. and 18.07c. for first and second quarters. A strike during most of August reduced the tonnage and increased costs coincidentally. Wages were advanced in July. Copper produced, 9,336,000 lb. for quarter.

RAY CONSOLIDATED COPPER COMPANY

Report for quarter ending September 30, 1919.

Property: mine, railway, and mill at Ray and Hayden, Arizona.

Operating Officials: W. S. Boyd, general manager; C. A. Smith, superintendent of mines; D. D. Moffatt, superintendent of mills.

Financial Statement: net operating profit, \$706,070; miscellaneous income, \$226,076; total income, \$932,147; dividend disbursements, \$788,589; net surplus for quarter, \$143,557.

Dividends: third quarter 1919, \$788,589; total to date, \$23,046,850.

Development: underground development consisted of 2606 ft. or a total to date of 694,671 feet.

Operations: copper produced amounted to 11,534,747 lb. in concentrates, and 136,222 lb. in raw ore shipped to smelter. Ore milled, 392,800 tons averaging 1.828% copper. This is 50% of the normal output before curtailment following the War. Mill extraction, 80.33%. Milling cost, \$1.33; net mining cost, \$1.76; net cost of copper, 15.53 cents.

CHIEF CONSOLIDATED MINING CO.

Report for year ending December 31, 1919.

Property: patented mining claims in the Tintic and North Tintic mining districts near Eureka, Utah. Also control of sundry other properties in same district.

Operating Officials: Walter Fitch, Sr., general manager; Cecil Fitch, superintendent; J. Fred Johnson, assistant superintendent.

Financial Statement: balance sheet shows accounts receivable, \$215,920; Liberty Bond investments, \$551,876; cash on deposit, \$325,674. Net returns from smelter during 1919 were \$2,343,926 and net after deducting charges \$664,720.

Dividends: during 1919, \$282,954 was distributed. Total to date, \$1,517,825.

Development: development footage totaled 25,937 ft. Work was done on both of the present ore-zones and the existence of a third zone below the 1900-ft. level is indicated. Water increased below the 1800-ft. level.

Production: 63,726 tons of ore was shipped of an average gross value of \$55.75 per ton. Silver-lead ore averaged 0.0589 oz. gold; 43.277 oz. silver; and 11.92% lead. 36,558 tons of 'dry' ore is included.

BUFFALO MINES, LIMITED

Report for fiscal year ending April 30, 1919.

Property: the Buffalo mine, Cobalt, Ontario.

Operating Officials: Tom R. Jones, superintendent.

Financial Statement: net income from sale of bullion and ore, \$658,491; miscellaneous earnings, \$16,187; total, \$674,678. Operating expense, \$409,503. Total expenses, \$503,439. Net profit, \$171,238. Balance sheet shows \$617,613 in quick assets including United States bonds.

Dividends: none since 1915. Total to date, \$1,360,000.

Development: 1015 ft. of development work brings total to 24,525 ft.; 20,000 tons of ore are available for milling purposes.

Production: mill treated 28,572 tons from mines, 2000 tons from surface stock pile, and 77,239 tons of old tailing. Bullion returns amounted to 625,786 oz. silver.

Book Reviews

The Iron Hunter. By Chase S. Osborn. Pp. 316, ill. The Macmillan Co., New York. For sale by 'Mining and Scientific Press'. Price, \$2.

This is an autobiography by a man who has had a most interesting career, and writes about it in a breezy style that conveys much of this interest to his reader. From his birth in a log-house in Indiana, through his boyhood struggles and vicissitudes, through his young manhood as a newspaperman in the early mining days of the iron districts of Wisconsin, Michigan, and Ontario, up to his entry into politics, including one stormy term as governor of Michigan, the book is full of interesting incidents in a career more than usually combative. The author says that one of the things that he learned early in life was that one should be as good an anvil as a hammer, be able to take blows as well as give them. This sound and courageous philosophy pervades the book; among all the struggles, physical and mental, that are described, there is not one that was not cleanly fought and frankly described to its conclusion, whether victory or defeat. The book obtains its title from the fact that Mr. Osborn has been all his life stimulated by the romance of iron ore; he has spent a large part of his time prospecting for iron in Ontario, and, during the winter, when prospecting in that northern country is impossible, he traveled and tramped through many foreign countries, studying iron districts and smelters. As evidence of the good purpose to which he thus directed his energies, the discovery of the Moose Mountain iron range stands to his credit. Those who are interested in iron mining will find in this book much general information concerning the industry all over the world, most of the facts given being based on the trained observation of an enthusiast. The districts of Wisconsin, Minnesota, Michigan, Ontario, Lapland, China, and Madagascar, are described with sympathetic insight, accompanied by notes on the use of iron by ancient peoples. The book, however, is not a treatise on iron ore, but is the reflection of a rugged and vigorous personality in all its manifestations, of which the search for iron ore was one of the more absorbing. Nevertheless, we do not believe that the reader will be disappointed where the subject of iron ore is dropped, for the adventurous and exceptional career of the author contains little that is not interesting, particularly when his growing prominence made him an active figure in politics. Mr. Osborn's comments on his contemporaries, many of them eminent nationally, are illuminating, and from an angle that is not often obtained. Perhaps the most interesting of these comments, in the light of recent events, is that referring to the consideration of Woodrow Wilson as a candidate for the presidency of the University of Michigan at the time of the death of President Angell.

In such a book, which is of interest to the engineer as well as to the general reader, we would have liked a few maps, to give a clearer concept of the regions discussed, together with more illustrations. Mr. Osborn's wanderings have taken him to most corners of the globe, from trails through the trackless 'bush' of Ontario to the ruins of prehistoric iron furnaces in the Malay Archipelago, and a set of carefully selected illustrations would have added much to the book. Likewise in places we have found the arrangement difficult to follow; the chronological order is abandoned frequently without apparent reason, resulting in some confusion as to what part of his career the author is discussing. Much of the book gives the impression of having been dictated by a busy man to his stenographer, and then hastily combined with other parts that were written in more leisurely fashion. The result is a lack of coherence that could have been obviated by a little careful revision; yet the reason back of this defect is also the reason for the book's greatest

charm: its simple and candid style, with all the appearance of unsophistication, has subdued the ego of the author in a manner seldom found in an autobiography. Mr. Osborn writes about himself, his victories and his defeats, with the same impersonal directness that he applies, for instance, to his description of the Mesabi range. We are frank to say that we enjoyed reading this book immensely, and we can recommend it heartily to anybody who likes a straightforward statement of the adventurous career of a clean sportsman and a good fighter.

L. A. P.

Mechanical Drawing. By John S. Reid. Pp. 226, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.

The author of this book is assistant professor of mechanical drawing at the Armour Institute of Technology, and the book appears to be based on the course given at that institution. It is a good textbook on the subject. An idea of the scope can be gathered from the chapter-headings, which are: Instruments and Their Uses; Drafting-Room Conventions; Freehand Lettering and Geometric Drawing; Orthographic Projection; Representation of Points, Lines, and Planes, Orthographic Projection Applied; Isometric Projection; and Working Drawings. In an appendix, additional matter is included on lettering and geometrical drawing, and shades and shadows and conic sections are also discussed. Another appendix contains what is perhaps the most distinctive feature of the entire book, namely, a summary of the answers to a questionnaire addressed to 200 leading drafting-offices and including 35 questions covering standards of practice from the kinds of dimension lines used to the method of noting changes on a drawing.

Elements of Refrigeration. By Arthur M. Greene, Jr. Pp. 451, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$4.50.

This is a thorough discussion of refrigeration including both the theoretical basis and the practical application. However, the work is arranged in such a way that the 'practical' man, whose training has not been sufficient to enable him to follow the mathematical deduction of formulas, will nevertheless find the book useful. After a brief introduction dealing with fundamental principles, the book considers the various methods of refrigeration. Then follows a discussion of the thermodynamics of refrigerating apparatus and a description of the various types of apparatus. Further discussion of heat transfer and insulation leads to the consideration of cold storage. Chapters following this deal with ice-making and with miscellaneous applications of refrigeration. The next chapter is devoted to costs and the final chapter to the solution of a number of problem dealing with practical applications of refrigeration.

Millwrighting. By James F. Hobart. Pp. 438, ill., index. The McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$4.

Under the term millwrighting, the author includes the construction of industrial buildings, and the book will be valuable to those engaged in both design and construction. The first few chapters are devoted to the laying out of buildings and the use of the various instruments employed for this purpose. Then come several chapters devoted to the erection of buildings and the design of structures, including the strength of materials. The remainder of the book may be said to deal with the special problems of the construction of industrial buildings. The several chapters discuss shafting, pulleys, belts and belting, setting-up machines, babbitting, steam and water-pipe fitting, erecting steam-engines, setting steam-boilers, water-wheel setting, and installing electric motors. The book is well-illustrated and the treatment is clear and suited to the needs of the 'practical' man.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

USE OF TRAILER WITH MOTOR-TRUCK

The accompanying illustration shows a three-ton motor-truck trailer manufactured by the Troy Wagon Works Co. put to excellent use. Together the truck and trailer are loaded with 21 light six touring car bodies, which is the number that can possibly be loaded in a 40-ft. railroad car. These bodies were transported from Muncie, Indiana, to Springfield, Ohio, a distance of approximately 100 miles. The round trip is made in 20 hours, and this includes the loading and unloading time. The average speed on the road is about 15 miles per hour. Under normal conditions it would require by rail, one week to get the bodies, which they

A. S. Winter, formerly advertising and sales manager for the Wm. Powell Co., has joined the sales force of **The Fairbanks Company**, Pittsburgh, Pennsylvania, and will represent them in southern Ohio.

R. A. Orrett announces that he has withdrawn from the firm of Griffin Company and has established offices in the Mills building, San Francisco, under the name of **R. A. Orrett Company**, whose services are available as general purchasing agents.

The Hardinge Company is distributing convenient loose-leaf sheets, suitable for filing in the Lefax note book, which give detailed information and data on grinding in ball and

Automobile Bodies Transported by Motor-Truck

get by overland transportation in 20 hours. Shipping the bodies by truck and trailer is a little more expensive than by rail, but owing to the delay which the railroads would cause there is economy in using truck and trailer, from the fact that deliveries are not held up.

In bad weather these loads are covered with a large canvas envelope which fits closely over the bodies on both the truck and trailer. The weight of each body will average about 500 lb., making a total load of only 10,500 lb. In this particular case, it is not the weight of the load that counts, for, as in many other cases, the load bulks considerably and there is still no weight of any consequence.

COMMERCIAL PARAGRAPHS

A catalogue entitled 'Reversible Ratchet Wrenches' has been issued by the **Lowell Wrench Company** of Worcester, Massachusetts. A complete line of wrenches for various uses is described and illustrated.

B. M. Snyder, for the past ten years in consulting practice in Los Angeles, has become a member of the **Southwestern Engineering Company**, of that city, and will fill the office of secretary and treasurer of the corporation.

tube-mills, based on operations at different plants. These will be followed by others of similar nature, and in the same convenient form.

The Booth Electric Furnace Co. has opened an office at Detroit in charge of M. A. Beltaire, Jr., at 805 Hammond building, and another at Birmingham, Alabama, in charge of Gassman & Cunningham, Brown and Marx building. The Booth company reports the sale of 20 rotating electric brass furnaces which includes a number of repeat orders. These orders cover all four sizes from 250 to 2000 pounds.

The Wheeler Condenser & Engineering Co. of Cartaret, New Jersey, has designed a new vertical jet condenser, the feature of which is a vertically split casing on the tall pump. This feature permits easy and quick removal or inspection of the pump-rotor or other internal part. It is now simply a matter of removing the bolts and cover, and uncoupling the rotor. Before this design was developed, considerable time was required to get at and remove the rotor.

'Centrifugal Pumping Machinery' is the title of Bulletin H-4, recently issued by **Lea-Courtenay Co.**, of Newark, New Jersey. The pamphlet sets forth in a clear and concise manner the features of the various types and sizes of centrifugal

pumps manufactured by the company. It is profusely illustrated with cuts of individual machines as well as with views in the company's shops, and installations of the pumps in various commercial plants throughout the world. The foreword says "quality is the most essential attribute of a pump", and this has been the aim of the Lea-Courtenay organization.

The Yuba Manufacturing Co. in the winter number of the 'Bulletin' features Model 20-35 ball-tread tractor. Two years ago an order was placed for a tractor with an over-size motor, designed to compensate for loss of power due to working at an elevation of 5000 ft. It was found that there was less wear and tear, that the clutches were relieved of overwork, and that the tractor gave a better performance in every way. Accordingly the standard 20-30 model is now equipped with the larger motor, and all orders will be filled with this style of machine unless otherwise specified.

The Chicago Pneumatic Tool Co. on January 21 and 22 held a general conference of executives, plant and branch managers, and salesmen at its Detroit plant on the occasion of the formal opening of a large five-story addition. At this conference the expansion program of the company for 1920 was outlined, calling for largely increased production not only at Detroit but at the five other American plants. It was reported that much of the proposed increase in production was already absorbed by orders for future deliveries. The nation-wide chain of 'service stations' which the company has opened and supplied with complete stocks of spare parts, machinery, and tools, and provided also with facilities for handling territorial repairs for users of the company's products, was also outlined in detail.

The Cutler-Hammer Mfg. Co., of Milwaukee, has made an addition to its line of enclosed starters. The enclosed feature removes all danger of exposed parts and protects the button and segment contacts from damage due to fine collecting dust or spraying water. This starter, known as Bulletin 2111, is very desirable for small direct-current motors in exposed locations driving line-shafts, fans, blowers, pumps, drills, and small motor-generator sets for arc welding. It consists of the familiar type of direct-current hand-starter enclosed in a sheet-metal case, having an external lever which engages the movable arm of the starter. The external, or operating lever, is insulated from the revolving contact arm by a block of molded insulation. A pointer on the lever and legends stamped on the cover indicate to the workman whether the starter is 'off' or 'on'. A low-voltage release-coil in series with the shunt-field protects the motor in case of voltage failure or if the field should be opened while the motor is running. Both the enclosed and open-face type starters are made in various capacities up to 50 hp., operating at 115, 230, and 500 volts.

R. E. Fulton, vice-president of the International Motor Co., warns shippers to prepare now to meet the emergency arising from congestion in railroad transportation. He says: "During the congestion of 1917, the motor-trucks in use hauled 1,200,000,000 tons of goods, and this year with production greatly increased and the railroads crippled by the coal shortage, the demands upon the trucks will be many times greater. The inability of shippers of goods to get satisfactory service from the railroads has already caused many of them to use motor-trucks, and if the present demand keeps up, the production of high-grade trucks to meet the demand will be impossible. It is significant to note that the sales of Mack trucks last month increased 58% over the month previous, and that this heavy demand is increasing steadily. Another point that shippers should not overlook is that the railroads will be turned over to their owners soon, and that increased freight rates, as a result of this, are inevitable. The Esch railroad bill, which aims to give the

railroads a helping hand during the period of transition, has provisions which stipulate that the railroads shall immediately apply for increased freight rates. This certainty of increased railroad rates as well as the inadequacy of the railroads to give the kind of service that is being demanded, points to an oversold condition in the high-grade truck market before very long. Business men in order to be sure that their freight will be handled should place their orders for sufficient motor transportation now, while deliveries are obtainable. The increased demand for trucks from foreign countries will also have a big influence on conditions. Export sales of Mack trucks last month were the biggest yet, many going to Peru, Cuba, Norway, Argentina, Holland, and Mexico."

'For the Glory of America' is the title of an attractive and unusual book published by the companies of which Samuel W. Traylor is the founder and head. These include the Traylor Engineering & Manufacturing Co., the Traylor Shipbuilding Corporation, the Cement Gun Co., and the Traylor-Dewey Contracting Co. The book is a record of the activities of these companies during the past five years. Its principle theme is the part that the various Traylor organizations played in the Great War, to the successful termination of which they contributed more than an ordinary share. They played a prominent and creditable part in the activities on the 'Home Front' which as they say "is that vast array of factories, extending throughout the length and breadth of this great country of ours, whose tireless activity furnished the wherewithal to do battle in the cause of Liberty". The manufacturing company made shells, marine engines, marine boilers, and the 'Master Road Builder' a combined elevator and crusher which did excellent service in making roads for the troops in France. When the call came for cargo boats, the Traylor Shipbuilding corporation was organized and was among the first to turn its energy toward the building of 3500-ton wooden ships. The Traylor organization has long enjoyed a world-wide reputation as a producer of mining, milling, and smelting machinery, and its enterprise and patriotism during the War entitle it to a deal of credit. No one can begrudge the Traylor companies the self-satisfaction which they express in this really handsome book.

Edward D. Kilburn, who since March 15, 1917, has been New York district manager of the Westinghouse Electric & Manufacturing Co., was recently elected vice-president and general manager of the Westinghouse Electric International Co. Mr. Kilburn graduated from Cornell University, and immediately entered the employ of the Westinghouse Electric & Manufacturing Co., for a number of years being at the Syracuse office of the company. Subsequently, he was transferred to the Westinghouse Machine Co. with headquarters at New Haven, Connecticut. In 1915 he returned to the Electric company as manager of the power division of the New York office. A year later he was also made manager of the railway and lighting divisions, subsequently becoming manager of the office. Maurice Coster, who has been actively engaged for more than thirty years in handling the foreign interests of the Westinghouse company, continues as vice-president of the International company with advisory duties. The president of the International company is Loyall A. Osborne, who is senior vice-president of the Electric company and was actively engaged in national work during the War, having been chairman of the executive committee of the National Industrial Conference Board, chairman of the committee of the Council of National Defense, a member of the National War Labor Board, and other important bodies. The Westinghouse Electric International Co. was formed in the spring of the present year to succeed the Westinghouse Electric Export Co. It handles the Westinghouse foreign business and is world-wide in its scope.

T. A. RICKARD, . . . Editor

IN our last issue we published an article on 'Mining Exploration', by Mr. J. H. Farrell, intending to draw attention to it, as it deserves. We venture to ask mining engineers to turn back to it, if they have not read it already, because it deals with an important subject, which Mr. Farrell has discussed in a suggestive manner. Contributions on the subject are invited.

AN interesting decision in a controversy involving the ownership of a mining claim in the Kirkland Lake district has been rendered by the Mining Commissioner of Ontario. The original locator of the claim proved that he had paid more than \$200 to certain miners, who, in return, furnished a sworn statement to the effect that they had properly performed the required assessment work. It appears, however, that they had falsified this statement and that in reality they had done nothing on the claim. A subsequent location was duly made and the Commissioner settled the contest that followed by deciding in favor of the re-locator. Despite some adverse comment, we believe the decision to be sound. While it may work some hardship on non-resident owners, the obvious opportunity for fraud, and serious complications that might develop whenever a claim became particularly valuable, would seem to put the alternative decision out of the question.

DELAY in the receipt of the text of Mr. Hoover's speech on February 17 compels us to place it at the far end of this issue. We are glad to give it verbatim to our readers because it is not only the speech of the president of the American Institute of Mining and Metallurgical Engineers, the organized body of our profession, but also the public utterance of a Presidential candidate, that is, one whom a large proportion of the American people regard as a candidate. Apropos of this, we were amused several months ago when we told a friend that Mr. Hoover had accepted the nomination as president; he, off his guard for a moment, looked keenly interested, but when we explained that it was only our Institute of which he was to be president, his look of disappointment was delightful. We do not depreciate the character or function of the Institute by telling the story; indeed, it is a happy coincidence that Mr. Hoover should have been elected to the chieftainship of the mining profession in the United States at this time when most engineers and other professional men all over our country are expressing a keen hope that he may be offered, and that he may

accept, the nomination to the highest office in the land. Those who read the speech delivered before the Institute will find further reasons for justifying them in their purpose to elect him not president only but President.

ENTRIES of lands covered by mining locations have been made by stock-raisers in Montana, and Mr. L. A. Fenner contributes a letter on the subject in this issue. It appears, on enquiry at the General Land Office, that claimants of valid locations made prior to any right to the land under the stock-raising Act of December 29, 1916, are entitled to both the surface of the claim and to the minerals covered by it, but as neither the local offices nor the General Land Office have records of mining locations prior to the filing of applications for patent, it becomes necessary for the mineral claimant, where his ground has been included within a stock-raising entry, to file a duly corroborated protest in the local land office, together with a request for hearing in order to establish the mineral character of the land and the prior initiation of his right thereto. We are much obliged to Mr. Fenner for calling our attention to this matter, which may concern many of our readers.

UPON another page we publish an article by Mr. Morton Webber on the sampling of mines. It is a subject on which he is an acknowledged authority and one which is of perennial interest to those engaged in mining, more especially to the engineer whose duty it may be to appraise mines for his clients. In the present article Mr. Webber responds to a request to describe in greater detail the use of mill-tests as a check on moil-sampling. More than two years ago he outlined this 'combination' method in our columns, and elicited a useful discussion, in the course of which other engineers asked for further information concerning this means of correcting conclusions based upon the ordinary methods of sampling with the moil and hammer, otherwise called hand-sampling. The idea is to detect the errors latent in the usual procedure by means of milling a considerable tonnage of ore from one or two representative stoping-areas. He does not discuss the subject of a preference as between sampling a mine by means of a few large lots of ore and sampling it by means of a great number of cross-sectional groovings, but he is advocating the use of the bulk method as a means of ascertaining the inaccuracies lurking in the fragmental method. Nor does he dwell particularly on the use of the mill-test as a

metallurgical experiment; he has in mind the one object of preventing error by means of a check. As an example, he describes his procedure when sampling a low-grade gold mine in Central America. This description serves to illustrate another feature of such technical work, namely, the variation in the degree of discrepancy between the hand-sampling and the mill-testing, which he recognizes and overcomes by decreasing the interval between areas subjected to milling, as the circumstances may require. He discusses the application of this combination method to low-grade copper mines and illustrates his suggestions by means of a diagram. We have found the article interesting and useful, and we feel sure that it will be appreciated both for its direct information and for its indirect suggestiveness. Any further discussion by experienced men will be welcomed.

WHAT line of attack the political machines intend to develop in their opposition to Herbert Hoover's candidacy is indicated by Mr. Samuel Untermeyer's assault upon Mr. Hoover appearing in the Hearst papers, which afford a fit medium for the purpose. To mining men who recall Mr. Untermeyer's association with the Guggenheims in the Nevada Consolidated deal, and with other phases of predatory finance, it was amusing to read the expressions of unctuous rectitude published last Sunday from the friend of Tammany Hall. Mr. Untermeyer, who has participated in many a shady mining deal, talks semi-religiously and on a Sunday about "the natural resources of the world that should belong to the people" and has the impudence to make sinister allusions against a man who by his public work during the five years of world crisis rose to the greatest heights of beneficent effort in behalf of the suffering peoples of the world and in behalf of the welfare of his own country. It is to laugh; of course Tammany Hall, Hearst, the Sam Untermeyers, and their like will fight Hoover. That is why the rest of us love him.

ATASCADERO is a euphonious Spanish name associated now with the publication in California of an attractive monthly periodical called 'The Illustrated Review'. The publisher is Mr. E. G. Lewis, to whose mine-promoting activities we have referred more than once. Somebody has sent us the latest issue of this magazine and has marked page 26. On turning to that page we note a report by Mr. C. E. Gilman on two oil ventures in Montana. We are told that "the formation bed is lime and the cap rock is soft shale". This is not exactly nonsense, but it is near it. The same remark applies to the report as a whole. Mr. Lewis explains that as editor of 'The Illustrated Review' he "has neither oil nor mining stock for sale" but "being personally interested in both these properties, through his corporate firm of Lewis, Gilman & Moore", he makes the following proposition to the readers of his 'Review': he will "present a one-twentieth interest in both" the Omega mine in Tuolumne county, California, and "his interests in the new oil-field" to each subscriber "sending in ten new subscribers

at \$1 for three years each or one new life subscriber at \$10". Here is another scheme for circumventing the Blue Sky law. Mr. Lewis is too generous, it seems to us, if the gold mine and the oil-field have any sort of value. To receive a twentieth of such potentialities of wealth as a commission on \$10 seems too much like giving things away, especially as the 'Review' is really a most interesting and attractive publication. Our advice, to anybody caring to have it, is to subscribe for Mr. Lewis's publication and take damned good care not to buy shares in any of his mining schemes.

AS the idea of discarding the use of silver in subsidiary coins has been suggested, the question of the best substitute is now engaging attention. The principal requirements are that the metal or alloy of the coin be durable and difficult to counterfeit. The Swiss government has recently made tests to determine the resistance to abrasion displayed by coins of various composition. Pure nickel far excels the rest; bronze is second, and a copper-nickel alloy is next, the others included in the test being brass, copper-silver, and various aluminum alloys. Nickel when alloyed with 5% of other metals loses its undesirable magnetic property, and likewise is tarnished with difficulty. Two properties of this metal make counterfeiting peculiarly difficult, namely, its hardness and its high melting-point. In consequence, heavy machinery is required to make the impression on the coin in the first place, and when once properly made it is so distinct and well defined that the imperfections of an imitation are detected easily. The high melting-point will oblige the counterfeiter to provide an elaborate plant for melting the metal and cutting his blanks. Since the actual value of the metal constituting subsidiary coins is comparatively unimportant, the good points of nickel commend it for serious consideration in selecting a substitute for the silver now used in the mints.

WHETHER Congress will agree to place a \$500 duty on tungsten, in order to protect our domestic production of that metal, we do not know, but we are interested to learn of an enterprise in Korea that bids fair to compete with the American producer most successfully. The Chosen Minerals Company controls a concession at Neigetsu, in Korea, that is unique. It is a scheelite placer. The gravel averages 45 feet in depth, 200 feet in width, and is two miles long. The scheelite is recovered by ordinary panning, the work being done by natives. The deposit averages 15 to 22% of which about 6% is lost, temporarily, in the tailing. The concentrate, which averages 70% tungstic oxide and is produced at the rate of 60 tons per month, is shipped to Liverpool, where it fetches \$7 to \$8 per unit. If the Japanese, who now control Korea, enact favorable mining regulations, it is probable that machinery will be placed on this placer for conducting operations on a larger scale. Meanwhile we are informed that the British are selling ferro-tungsten at 62 cents per pound, whereas it costs a dollar per pound to produce this alloy in the United States;

therefore, despite a 'differential' of 25 cents per pound, established on account of a better quality of material, the British product has a margin of 13 cents per pound on which to invade our domestic market.

IN this issue we publish an article on the valuation of oil properties—or, more properly, oil mines—for the purpose of determining the amount of the invested capital on which exemptions from the Federal income-tax are to be calculated. This is a matter of vital importance, because, if, for example, an oil venture that was capitalized at \$100,000 in the early days of oil exploitation, say, 20 years ago, succeeded in developing a \$1,000,000 enterprise, it has, according to law, an 8% exemption before the reckoning of the net profit begins, whereas if the corporation does not obtain a valuation of its property as of March 1, 1913, as allowed by law, whereby its capital is established at \$1,000,000, which was its true value, then the corporation will suffer a loss of \$72,000. The article is based on a report prepared by a committee of five Californian engineers, who were requested by the oil companies of California to make the investigation in order to aid the Internal Revenue Commissioner, as well as the owners of oil ventures, in ascertaining the best method for valuing this form of property. The report was not made as a brief for the oil companies, but on the understanding that it would be welcomed by the tax authority.

LAST week we discussed the award of a gold medal to Mr. Sulman by the Institution of Mining and Metallurgy, in London, on account of his "contributions to metallurgical science", particularly flotation. In a previous reference to the matter we criticized Mr. Sulman's failure to acknowledge the writings of precedent authors. In a later bulletin of the Institution we find an article on 'Froth Flotation: Its Commercial Application and its Influence on Modern Concentration and Smelting Practice', by Mr. Walter Broadbridge, metallurgical engineer to the Minerals Separation company. Capt. Broadbridge made an honorable record in the War and he is a man of the highest standing in the profession; we have no prejudice against him, quite the contrary, of course; but this paper of his is open to the same criticism as Mr. Sulman's in that it ignores all previous writings on his subject. Mr. Sulman discusses the physics of the flotation process; Mr. Broadbridge describes the machinery and methods used in applying it to the treatment of ores; both these gentlemen utterly ignore the papers published by the American Institute of Mining Engineers and by the American technical press during the time when they themselves chose to remain silent. Nearly all the information in Mr. Broadbridge's paper has appeared at various dates during the last five years in publications that should be accessible to him, and certainly are accessible to other members of the Institution. We would like to know whether the officials of the Institution in London have decided to disregard the unwritten rule that an author make acknowledgment of precedent writings on his subject, or is the infraction of this etiquette to be approved on the part only of the Minerals Separation

staff? We venture also to ask why the council of the Institution failed to award the second gold medal, the one placed at its disposal by the Consolidated Gold Fields company to Mr. Broadbridge. Surely he is entitled to it, if Mr. Sulman is worthy of the premier prize. Putting aside the books on the subject published in this country while Messrs. Sulman and Broadbridge, willingly or unwillingly, were muzzled into silence; putting aside the voluminous contributions on the subject published in the 'Mining and Scientific Press', we ask how the council of the Institution, or whoever may be responsible, explains the manifest discourtesy to the American Institute of Mining Engineers in ignoring the valuable papers on the subject that appeared in the Institute's transactions, particularly in 1915 and 1916? Moreover, we ask again whether the Institution intends to place a premium on silence and on secrecy in the metallurgical art? The printing of these belated papers by the metallurgists of the Minerals Separation company, coming forward now with information that is years old, after their company had tried ineffectively to prevent the publication of such information by others, constitutes an impertinence, rendered all the more marked by the deliberate failure to make references to the current literature of the subject.

The Leasing Act

After a long fight in Congress the Leasing Bill, S. 2775, has been passed, with many amendments. The last clause to be adopted was the last paragraph of Section 19, which now reads: "All permits and leases hereunder shall inure to the benefit of the claimant, and all persons claiming through or under him, by lease, contract or otherwise, as their interest may appear: Provided that no claimant acquiring any interest in such lands since October 1, 1919, shall secure a permit or lease thereon under this section." The Bill provides that 10% of all moneys received from sales, bonuses, royalties, and rentals, except those from Alaska, shall be paid into the U. S. Treasury, leaving 37½% to the individual State and 52½% to the U. S. Reclamation Fund. This distribution was the result of protracted debate, ending in a compromise. Only minimum royalties have been fixed, not the maximum, which are left to the discretion of the Secretary of the Interior. The maximum area for a lease is fixed at 3200 acres for oil-lands, 2560 acres for coal, and 5120 acres for oil-shale deposits. This legislation is a complete reversal of the original land policy of the United States, which gave the right of patent for oil and other mineral lands, but rendered the privilege ineffective by a series of withdrawals of large areas by Presidential initiative, which the Department of the Interior followed by a policy of additions to the withdrawals, even in partly explored areas, after making secret investigations and filing secret reports. About 46 million acres of supposed coal-land in the West, about six million acres of supposed oil-land, and about three million acres of supposed phosphate-land are now opened to exploitation under a permanent leasing system. The fight has been long and costly, involving

a bitter controversy between those favoring Federal control as against State rights and affecting the long-drawn litigation arising from the withdrawal of oil-lands in California and Wyoming under the Taft administration. How many of the pending lawsuits will be quieted by defendants taking advantage of this enactment, remains to be seen. Many favorable oil-bearing formations will be thrown open to exploration, and a vast area of oil-land in Alaska will be freed for development. There will be a rush to Cold Bay, Ilimania, and other districts in southwestern Alaska at once. Undoubtedly many phases of mining in the West will be stimulated by the greater freedom for prospecting in various parts of the national domain, and for that reason the mining community welcomes the Act.

Goldfield Consolidated

The preparations of the Goldfield Development Company for re-starting the old Consolidated mill to treat the remnants of ore in the old Mohawk, Combination, Red Top, and January claims, mark the beginning of another, and perhaps the last, chapter in the history of this rich bit of Nevadan desert. At the time when dozens of abandoned silver-mining districts are being rejuvenated and their mines re-opened after years of idleness, it is interesting to see that Goldfield, younger by a generation than the rest, more spectacular at its zenith, is also, as the local scribes would say, 'staging a come-back'. To those who have followed the career of Goldfield there is a tawdry romance in its history. The first discovery was made late in 1903 and during the two following years many claims, the January and Combination among them, were opened up; a number of small stamp-mills, in which amalgamation and concentration were followed by cyanidation or chlorination, were successfully operated, and later the railroad was extended from Tonopah. Then in 1906 the district started to boom; it became a little rougher and a little wilder each day until at the time of the Gans-Nelson fight on September 15, 1906, it was the rendezvous for the 'sporting' element from all over the country. Then came the first labor troubles, when George Wingfield, in the face of solemn warnings that anyone distributing a certain newspaper would meet instant death, advertised that at 12 o'clock noon he would sell the paper. This he did, walking out of Cook's bank with a six-shooter in each hand, thereby 'calling the bluff' of the union men and 'getting away with it'. It was not long before the mushroom camp had grown into a city of 30,000, including miners, gamblers, speculators, brokers, and adventurers of every kind. The old Northern saloon never closed its doors; for 24 hours each day and 365 days each year it welcomed patrons to the bar, the 'wheel', the 'bank', to 'stud', and to 'craps', 'earning' for its owners no less than \$100,000 net for many months in succession; and the Northern was one of 30 as popular, if not so well known, resorts. Meantime the lessees, among them the Francis-Mohawk and the Hayes-Monette partnerships, were gouging marvelously rich ore from the old Mohawk vein, the latter taking \$5,000,000 out of a

block 370 by 150 ft. Miners would refuse \$20 per day for work on development, preferring to accept \$5 on a lease that was in ore. No one, not even the assay-offices that bought the mineral, will ever know the value of the gold 'high-graded'—that is, stolen—by these miners. So rich was the ore and so short the time that a 50-horse-power hoist and eight rock-drills were sent from Chicago by express on the Overland Limited, so the story goes. Then the late George S. Nixon and George Wingfield organized the Goldfield Consolidated, which finally included the claims mentioned above together with the Jumbo, Red Top, and others. Mr. J. H. Mackenzie was resident manager for the company, and while still running the Combination plant, he built, in 1907, the new mill, a modern cyanide plant with 100 stamps. Mr. J. W. Hutchinson, who worked out an ingenious scheme for cyaniding the rich sulphide-concentrate, became superintendent; later he increased the capacity of the mill to 900 tons, and, including shipments of high-grade ore, the mine was producing nearly a million dollars per month in gold bullion. But the glamor was gone. The 30,000 inhabitants soon dwindled to 4000, and in September 1910 the law forbidding gambling in Nevada went into effect, and the last of the deft-fingered gentry migrated to more fruitful fields. Mr. J. R. Finlay managed the Consolidated during that year and he was largely instrumental in equipping the property for the lean years at hand. It was about this time that a certain elderly farmer from Massachusetts sent to Mr. A. H. Howe, treasurer of the Consolidated, an old certificate for a few hundred shares of Mohawk stock, which he had purchased for nearly nothing long before the consolidation; he asked that, if the certificate was worth anything, the proceeds be forwarded, and to his surprise he got a check for something over \$30,000, as Consolidated stock was then selling at \$20 per share. One wild-cat had made good! Later Mr. Albert Burch served as manager for a time and then Mr. Hutchinson was deservedly promoted to the position of general manager. The grade of the ore diminished; the old tailing from the cyanidation of the concentrate was roasted and most of the gold recovered; flotation was introduced, and used with some success, but the reserves of ore were being exhausted, costs were rising, and the Consolidated suspended operations in 1918. The district survived even this. Now comes the Development company, with a plan to cave large portions of the old workings, including pillars of ore and waste, and the stope-filling, and to treat the mixture in the Consolidated mill. During the operations of the Consolidated company hundreds of samples were taken daily to determine what material was ore and what was not, because it was impossible to distinguish by appearance; it seems reasonable to suppose that a good deal of valuable rock went into the stopes for filling, and it is quite possible that a satisfactory mill-feed can be obtained by recovering pillars and filling together, by a system of caving and glory-holing, as is planned. We wish success to this new departure, which is in the competent hands of Mr. A. I. D'Arcy.

DISCUSSION

Prohibition

The Editor:

Sir—As the author of the "kick" against prohibition referred to in your issue of January 24, may I comment very briefly on your article on the subject.

You quote as foolish a man that pledges himself to vote against any candidate for public office, regardless of party affiliation, who favors the enactment of prohibition. There are thousands of men in Canada and the United States who have taken the same pledge as a protest against the folly and hopeless stupidity of the Act, which will make law-breakers, liars, and hypocrites of many erstwhile good citizens.

To accept quietly and good-temperedly a bad law that curtails the privileges of thousands for the sake of a few weaklings is not my idea of good citizenship or government by majority. Your article says: "Prohibition is a standing example of the fact that if you say the same thing often enough it will be believed by the average man." This is true also of Canada. We have had trick ballots, mis-statements, false statements by so-called evangelists. The frightful degeneracy of Great Britain has been drummed into us. If by tactics such as these he gets his laws enacted, I presume the citizen that does think must fold his hands and accept the inevitable.

If the early settlers in the U. S. A. had accepted the decision by the majority in England that they should pay taxes without representation, there would not have been any U. S. A. But these settlers, being liberty-loving people, made their kick and did not accept the decision of the majority with good humor.

Your article touches on the strict regard for the constitutional rights of the citizen. The average prohibitionist cares nothing for the constitutional rights of any citizen. He is out to fine or imprison any one (whether he abuses liquor or not) that will not obey the intolerant and tyrannical laws he has enacted. That this attitude is undemocratic and is class legislation of the worst type does not bother him, as he can always get some half-baked legislator or hysterical parent to back him up.

The concluding paragraph of the article is stock prohibition stuff. The drunkard's wife and the temptation to the child always (like the death of Lady Isabel in East Lynne) brings down the house. The "I didn't raise my boy to be a soldier" sentiment is dear to the heart of a prohibitionist.

There are today scattered over France, Belgium, and many other parts of the world the bones of many of Great Britain's best sons. Many of these were public

school lads who left home at an early age to receive their education. When the call came, they went and did their duty, and it is well to remember that most of the parents of these lads had what is far better than silly laws—a supreme confidence in the manhood of their sons.

There is little credit to be gained in raising a boy as a hot house flower, if after he takes his place in the world, he cannot resist temptation.

In conclusion, Sir, I cannot congratulate you on your article. To class as fools people that respect the rights of others and are in favor of a sane government is not good argument, as good citizenship calls for individual thinking and effort, not blind obedience to the mob—although (as Stephen Leacock says in his admirable article against prohibition) "one always has the privilege of leaving, and living in the South Sea Islands or some civilized country. Let us thank God for this amount of freedom".

F. J. BOURNE.

The Mining Industry in Australia

The Editor:

Sir—As one, who has contributed his share toward the mining and metallurgical development of Australia as witnessed by the period from 1888 to 1914, I was naturally interested in the resumé on the present state of the mining industry in Australia written by my capable friend Mr. F. H. Bathurst, and published in your issue of January 31.

His clear and concise summing up of the causes, which have been mainly responsible for the depression prevailing at present in a once prosperous industry, leaves no doubt that the end of mining for non-ferrous metals can be foreseen within measurable time, and that, in the absence of new discoveries, the future of Australian mining and metallurgical development will be restricted to iron and coal and possibly to a few hydro-electric installations for the treatment of Broken Hill and Tasmanian zinc concentrates. Obviously the success of the latter would depend greatly on the ruling price for spelter, and such economic factors as coastal and over-sea freight-rates.

Mr. Bathurst, in the opening paragraph of his article, makes brief reference to the attempt of Mr. Hughes, the present Prime Minister of the Commonwealth, to eliminate forever the so-called dominance that the large Ger-

German metal houses are supposed to have exercised over the metal trade of Australia. During the War the group of German metal-merchants interested in this business was conveniently referred to as the 'metal octopus', with the apparent intention to convey to the world at large the magnitude and character of a monster sucking the very life out of the Australian mining industry. As no attempt has ever been made to submit a different version, it may be of general interest to analyze somewhat closer the above contention, in order to arrive at the actual condition of the Australian metal business, as it existed shortly before the War. Having been for many years a producer of metal and furnace products in Australia, mostly on behalf of English and Australian concerns, I am perhaps qualified to speak with authority on the whole question involved.

In the first place, it was customary for all large mining and smelting companies that were in the open market for the sale of their products to invite tenders and to sell to the highest bidder, whereby British, Belgian, and American metal-refiners and merchants had the same opportunity to compete for the business as the German metal firms. That the German houses have been more successful in their bids, speaks, after all, well for their superior organization, more particularly in connection with the business for Broken Hill zinc concentrates. The latter, of course, was so much involved with shipping rates for Europe, that these were at times a deciding factor in securing or losing a given contract.

Considering now that the price of spelter previous to the War stood under £26 per ton, I maintain that the German metal firms in spite of it enabled the Broken Hill mines to dispose of their zinc concentrates at a profit and thus placed them in a position to fully develop the various flotation processes that are now in use at Broken Hill and elsewhere in the world.

The period of this development falls into the decade previous to 1914, and I am sure there are many Australian mining men today who, in all fairness, will admit that the strictly commercial services rendered by these German metal firms were on the whole satisfactory and to the benefit of the Australian mining industry.

So much has been said and written about a deep-laid German conspiracy, which had the object of monopolizing the Broken Hill zinc concentrates to the detriment of Australian and British interests, that it is about time to tell the truth. The whole business was one of gradual development, and as British zinc-smelting works failed to rise to the opportunity and Americans were handicapped by excessive freights, the German metal houses secured the business *only* by providing the additional furnace-capacity, which was required to handle the increasing tonnage of Broken Hill concentrates. As this involved a large capital outlay it was, of course, necessary to make lengthy contracts for concentrates, and that is about all there is to the great conspiracy. That the Germans after all may be the losers by their greater enterprise, Mr. Hughes does not tell us.

However, I am making these correcting statements

without any animosity toward Mr. Hughes; he no doubt thought of fulfilling a great patriotic duty, when he decided to eliminate the German metal-buyer from Australia forever, though it reminds one somewhat of the man who cuts off his nose to spite his face.

I hold no brief on behalf of the German metal-merchants, neither am I under obligation whatever to any of them, but, having in pre-war times done business with them, I am not afraid to raise my voice in protest against all the misleading statements which have been spread about this Australian metal business.

New York, February 11.

E. A. WEINBERG.

[Mr. Weinberg is well known to us by reputation, and we are glad to publish his letter. The apathy and lack of initiative displayed by the English and Australian dealers in metals, particularly those engaged in the metallurgical business, did undoubtedly play into the hands of the German Jew combination, but that does not alter the fact that the Zinc Kartel and other German metal-buying organizations did use objectionable methods, more particularly in their relations with the Belgian zinc-smelting establishments. Combinations are unpleasant at their best, and the mining industry of Australia, as of the United States, will be wise in trying to frustrate the formation of any such combination of Jews or Gentiles as may obtain the power to throttle its industry by obtaining complete control of the refining and selling of the metals.—EDITOR.]

Stock-Raisers and Mineral Lands

The Editor:

Sir—I am herewith enclosing information that I thought might be of interest and help to the mining fraternity. I read in your paper about a year ago where one of your subscribers, by name, Bush, down in Arizona, had valid mineral locations on a copper lode, and one of the big cattlemen had a cowpuncher file on a stock-raising homestead that included mineral locations. Said Bush appeared to think the mineral locator was thereby wiped off the map. A case somewhat similar took place in this county. A party had several placer locations on which he had done the required assessment work for years, in fact, he had made his home on the land, had a garden, etc. Along comes another party who files a stock-raising homestead entry including therein mining locations. In the course of human events, said entry is allowed by the Land Department, and the entryman gives mineral locator notice to get off the earth. Others in the same locality have been and are up against the same proposition of contesting their homestead claimants. And I have been bucking one of the breed for three years as one of six placer locators; and only succeeded in getting part of the entry disallowed. And another entryman grabbed the whole of the location in another section before I knew he had even filed on the land. The intention of the homestead law is all right; but it doesn't always work out in practice as intended. Here in Montana the sheepmen and cattlemen were grabbing big chunks of landscape

under the 320-acre homestead law by putting a herder or puncher on for a few months each year; then along comes the 640-acre act which gives them a chance to annex bigger chunks. Sheepmen even go so far as to offer an outsider \$3000 or \$4000 to file and prove up on a homestead. Sheepmen get to fighting among themselves out on the open range; and land under fence is more desirable. The range for the cattle and horses belonging to small owners is becoming more restricted every year.

Under the rules for filing upon stock-raising homesteads, all mineral rights are reserved to the United States; a mineral locator has a right to go upon lands included in a homestead to prospect, mine, and remove the minerals therein during the time the entryman is proving up; also after issuance of patent. If I understood my lawyer-friend aright, in practice it works out that once a homestead entry is allowed, the sign up for the mineral locator is: "You can look but you must *not* touch." Verily the way of the lawmaker passeth understanding.

L. A. FENNER,

Virginia City, Montana, February 5.

Antimony and Its Uses

Antimony occurs chiefly in the form of sulphide or oxide in deposits which contain only antimony, or else is associated with lead, with lead and silver, or with gold. Many lead ores contain small amounts of antimony and in the processes of lead-smelting the antimony is collected as a by-product known as hard or antimonial lead, containing 5 to 7% antimony. It may also be made by mixing antimony ores with lead ores and smelting them together. This hard lead has a great variety of uses. For the ten years preceding the War the production of antimonial lead in the United States ranged from 10,000 to 15,000 tons per year, roughly two-thirds of this amount being produced from domestic ore, and one-third from imported ore. Antimony and its compounds have a great variety of uses. Besides that already mentioned the principal are the making of bearing-metal alloys, many of which contain considerable amounts of antimony; type metal, to which antimony imparts the property of expanding on solidification, thus yielding perfect letters; Britannia metal, used for tableware, toys, and so forth; and for a variety of minor purposes. A lead-antimony alloy is also coming into use for the sheathing of electric cables. Antimony sulphide is used in making matches and also in making red rubber. The oxide is used in making enamels and as a substitute for tin oxide in making bath-tub enamels and is quite important.

All of these uses, however, do not bulk very large in the metallic output of the world, and before the War antimony was considered a minor metal. The War changed this by creating a large use for antimony in shrapnel bullets, which contain 12% or more of antimony. The result was a large increase in production and price. The price, which before the War had ranged from 7c. to 8½c. per pound, rose to 40c. per pound in December 1915, and fluctuated during the War period, according to

trade conditions and also as military opinions varied as to the relative value of shrapnel and high-explosive shell in combat work. After the armistice the price rapidly declined and recent quotations have been about 9c. per pound. Presumably the stock of shrapnel on hand in the different countries is amply sufficient as a reserve stock for possible future wars, so that this use for antimony may be considered as non-existent and may possibly never occur again if the League of Nations proves effective, or if some substitute for shrapnel is discovered before another large war occurs.

TWENTY-EIGHT GOLD DREDGES were operated in Alaska in 1918, producing \$1,125,000 worth of gold, according to a report on the Alaskan Mining Industry just issued by the U. S. Geological Survey. Twenty-one dredges were in Seward Peninsula, three in the Iditarod district, and one each in the Fairbanks, Circle, Yentna, and Kuskokwim districts. These dredges handled about 2,490,000 cu. yd. of gravel. In 1917, 36 dredges handled 3,700,000 cu. yd. of gravel and recovered gold worth \$2,500,000. The average recovery of gold per cubic yard was about 57c. in 1918 and 68c. in 1917. The gold dredges of Seward Peninsula produced gold worth \$466,000 from 1,164,000 cu. yd. of gravel, making an average recovery of 40c. per cubic yard in 1918. The dredges of the Alaska Yukon districts produced gold worth \$881,000 from 1,125,000 cu. yd. of gravel, with a value per cubic yard of about 78c. Though dredges were built for use in the Alaska Yukon as early as 1898 and at Nome in 1900, this method of placer mining did not reach a profitable stage until 1903, when two small dredges were successfully operated in Seward Peninsula. Dredging began in the Forty Mile district in 1907; in the Iditarod, Birch Creek, and Fairbanks districts in 1912; in the Yentna district in 1916; and in the Kuskokwim region in 1918. A new dredge was installed in the Fairbanks district in 1918 and may have begun operating late in the season. The new dredge on Candle creek, in the Kuskokwim region, was completed in 1918 and operated for a short period. Up to the end of 1918 gold to the value of \$19,035,000 had been mined by dredges. The relatively low recovery of the dredges in 1918 was due, in part, to the unusually large amount of frozen ground encountered in Seward Peninsula.

IN view of the wonderful attainments of the safety movement in the past few years, during which time the hazard of the mining industry has been greatly reduced, it is believed that all risks can be lessened. Personal injuries will always accompany industrial activities. Mining will never be free from accidents, for many of its hazards are inherent to the industry, but the progress already made gives assurance that all such hazards can be greatly reduced. Safety measures are not intended to eliminate the need of personal thought and alertness, as careful men are always better than safety devices, but are essential for the protection of workmen who carelessly or unavoidably expose themselves to existing dangers.

A Chemical Laboratory

By JOHN C. MORGAN and EDWARD P. BARRETT

The large volume of analytical and chemical work in connection with metallurgical testing at the station of the U. S. Bureau of Mines at Salt Lake City made it necessary to have a laboratory equipped with all the appliances used in the rapid and accurate determination of the common elements. It is advantageous that results on tests be known not later than the day following the tests and these analyses must be accurate because all metallurgical testing is dependent upon the chemical analyses of the products.

The floor-plan is illustrated in Fig. 1, which shows that everything is compact and convenient. The chemist can stand in front of the hot-plate and transfer a series of beakers from the plate to the filter-table. The end-com-

Each of the filter-tables is fitted for 40 filtrations, the back row of funnels draining into a trough. The use of this row of funnels in filtrations from which only the precipitates are desired saves considerable time, for it is not necessary to place a beaker to receive the filtrates, and, of course, this decreases the amount of glassware needed, besides eliminating a great deal of dish-washing. The general plan of construction of the table-tops is clearly shown in the photograph. These tops are so made that the funnel-racks can be quickly removed, giving a flat-top table for use should necessity demand. Each table has three drawers in which may be placed filter-papers, cover-glasses, stirring-rods, etc. A shelf the entire size of the table is placed about eight inches above the

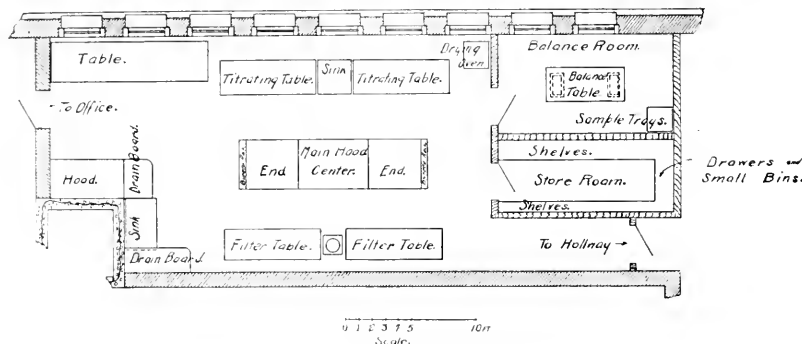

FIG. 1. FLOOR PLAN OF LABORATORY

partments of the central hood are each equipped with large gas-heated hot-plates. These two hot-plates and two filter-tables are arranged so that two chemists may work at the same time without interfering with each other's work. The central hoods have sliding windows so that the hot-plates may be used from either or both sides, which is a great advantage in titrating, especially in case the titration is made in a heated solution, since the titrating tables are directly opposite the hoods and in the same relative position as the filter-tables. The large sinks and drain-boards are placed so as to serve the hoods, filter, titrating, and general work-tables. The hood and work-table in the end of the laboratory are arranged for any special work, making an individual laboratory without isolation.

Fig. 2 shows the filter-tables, sink, and drain-boards, the three-compartment central hood, an end view of another hood, the hot and cold distilled water systems, and the motor-driven exhaust fan connected to the hoods.

*Published by permission of the Director of the U. S. Bureau of Mines. The photographs are by R. E. Head.

floor, thereby affording a convenient place to keep the trays of beakers and flasks, and it may also be used for reagent-bottles. Each table is supplied with a connection to the main vacuum system, so that it is also possible to make suction-filtrations on this table.

The large sink in the background is two feet by four feet, inside dimensions, and is supplied with hot and cold water. There are two drain-boards, one of which is two feet by five feet, and the other two feet by three and one-half feet.

The central hood has three compartments, the end compartments each being equipped with a gas hot-plate 36 by 18 inches. A plate of this size is large enough to accommodate all the heating operations necessary to keep one chemist busy with routine analyses. On the outside of the ends of the hood are supports for the 250-cc. dispensing-burettes, which are used in place of the ordinary 8 or 16-oz. reagent-bottles for the common acids. See Fig. 3 for a view of these supports with the dispensing-burettes in place. Also note the funnels underneath each burette to catch any drip and prevent acid from getting

FIG. 2. INTERIOR OF CHEMICAL LABORATORY

FIG. 3. ANOTHER VIEW OF SAME

on the floor. There is a shelf under the hoods on which the reagents are kept, 2½-litre bottles being used for this purpose. The central compartment is equipped with an electric furnace of the replaceable unit type and an electrically heated water-bath. The electric furnace is used for all ignitions of precipitates, annealing of gold beads, determinations of ash in coals, and sintering of ores in the determination of sulphur by the Eschka method. The hoods are piped with gas, water, vacuum, compressed air, and drain systems, and are supplied with 220-V. A. C. circuits. A Sirocco exhaust-fan, driven by a one-horsepower motor, removes fume from the hoods.

A shelf on the outside of each end compartment of the hood carries the tanks for the distilled-water, which is piped through copper tubing to each filter-table, to each compartment of the hood, and to the titrating-tables. One tank is fitted with an electric-heating device that furnishes hot water to the filter-tables in a short time after closing the switch, the other tank supplying cold water.

Fig. 3 shows the opposite side of the laboratory from that shown in Fig. 2. The opposite end of the central hood with the dispensing-burettes and supports is shown in the centre. At the right in the immediate foreground can be seen part of the fourth hood, which is equipped with an electric hot-plate. On the left is a general work-table, showing the drawers and the shelf underneath. This table is connected to gas, water, vacuum, compressed air, and drain systems, and with the hood opposite is used for special work.

In front of the central hoods are two titrating-tables between which there is a large sink, fitted with a device for maintaining a constant water-level, so that it may be used for the rapid cooling of heated solutions. This is a great convenience, especially when the chemist is making a large number of routine determinations. The shelves above these tables are for the bottles of standard solutions and are of sufficient height so that the siphons will easily fill the burettes. The supports for the shelves are made from standard iron pipe and fittings, as are also the supports for the burettes. These supports are painted dull black and the table-tops are painted white in order to furnish good lighting conditions for titrating. Each table is made with drawers long enough to accommodate burettes and with a shelf underneath. At the other end of the titrating-tables is an electrically-heated constant-temperature oven.

The door in the background leads into the balance-room, in which are three balances: an Ainsworth pulp-balance, a Hüsser automatic, and a Keller button-balance, all placed on a table supported by two concrete piers.

All samples are placed on wooden trays where they are kept until the analyses have been completed. The beakers and flasks, after being washed, are placed on wooden trays of proper size to hold 20 beakers or flasks; these trays when not in use are placed on the shelves beneath the filter-tables. Folding supports are available for holding the trays in the balance-room while samples

are being weighed into the beakers or flasks or other container preparatory to analysis.

Galvanized-iron trays, each of which will hold 30 cups, are used for holding annealing and parting cups.

Wall-plates connected to a 110-volt circuit are available at each filter-table, in the fourth hood, at the general work-table, and at the titrating-tables, so that any special electric lighting or heating device may be attached.

Fig. 3 also shows a convenient arrangement for the sintering of ores in the determination of potash, according to the J. Lawrence Smith method. This equipment is on the general work-table and is not in use constantly, but in no way interferes with the routine work.

A store-room adjacent to the balance-room is conveniently fitted with shelves, drawers, and cupboards. A basement store-room, the entire size of the laboratory, is situated immediately beneath it. The compressed air and vacuum systems are connected to motor-driven air-compressors and vacuum-pumps, which, with the air-receivers and tanks, are also placed in this room.

THE 'ATLAS OF COMMERCIAL GEOLOGY' is a publication under course of preparation by the U. S. Geological Survey. The study of foreign mineral deposits and supplies by the Survey has for years been incidental to the published annual inventory of the mineral production and resources of the United States. During the War, however, this study took on new importance, and work was begun on the study and distribution of the world's reserves of the essential minerals, resulting in the compilation, for the use of the Government, of a world atlas showing the production and resources of the more important mineral commodities. After the data thus compiled had served the immediate confidential needs of the Government itself, the Secretary of the Interior warmly endorsed the proposal to prepare the material for publication, so as to make it useful to the general public. The 'Atlas', the first part of which is now in press, will exhibit graphically the distribution of mineral production and of mineral reserves. An effort is made to give the necessary world view by means of mineral maps of every continent. The basic importance of the raw-material resources to the country makes it a prime public duty of citizens generally to know the facts regarding the mineral industry, and to ascertain these facts the intensive study of our own resources is not enough; we must also acquire a comprehension of what minerals other countries contain to supplement what we have at home. If it were possible to construct a composite diagram showing either the current output or the future reserves of the essential minerals in all the countries of the world the graphic exhibit would show so large a centralization in North America as to suggest that here is a group of nature-favored nations. Yet the present industrial demands for fuels, metals, and other mineral raw materials force the American business man to look beyond the present decade and beyond the borders of the United States.—Annual Report, Director U. S. Geological Survey.

The Combination Method of Mine-Sampling

By MORTON WEBBER

In respect to the 'combination' method of sampling large low-grade ore deposits, devised by me and described in the 'Mining and Scientific Press' of September 27, 1917, I note that several engineers have asked me to enlarge upon some important questions that have arisen from the correspondence on the subject. Before proceeding, I take this opportunity of thanking the following engineers for their contributions on this method of sampling, namely, R. E. Raymond, E. P. Spalding, Charles Bennett, Albert Burch, F. F. Sharpless, L. R. Parsons, H. R. Sleeman, and A. R. Pierce. The subject of mine-sampling is old; and it is, therefore, flattering to have evolved something that may be new and of sufficient importance to merit discussion for over two years.

The discussion had its inception in the discrepancy between the mill-feed and what was expected by sampling the ores of the Alaska Gastineau mine. The discussion brought forth controversy on the merits of hand-sampling versus mill-tests.* The predominance of opinion was in favor of hand-sampling. In this I concurred. I took the view that a mill-test referred only to conditions relatively close to the place from which the results were obtained; that by turning a mill-test of medium size into a big one, if the ore continued to come from the same place, it failed to throw additional light on areas remote from the test, which might be vital to the success of the enterprise.

The mill-test automatically eliminates and discloses the sampling-error, but, as stated, the information is confined largely to the place from which the ore is removed. Hand-sampling, on the other hand, furnishes the mineral content of the deposit over the size of the mass sampled; it contains a latent error (should such be existing), and the mill-feed estimate will be vitiated to this extent.

One of the principal exponents of hand-sampling was L. R. Parsons. He recommended hand-sampling as being infinitely more reliable than mill-tests, and, as I remember it, advocated that hand-sampling about 4 or 5 lb. per foot at close intervals was more reliable than heavy sampling, about 10 lb. per foot, at wider intervals. His intention was to utilize the law of average to a maximum.†

*The term 'mill-test' indicates a metallurgical experiment. Its use in the 'combination' method is not in respect of metallurgy, but of mine-sampling. The term 'bulk sample' is better. The incorrect use of 'mill-test' arose in an early contribution to the subject entitled, 'Mill-Tests v. Hand-Sampling'.

†In conducting a large examination I am in favor of heavy sampling, about 8 or 10 lb. per foot at intervals of 10 ft., against a 4 or 5-lb. sample at 5-ft. intervals. If the mine is 'spotty' and will not stand a 10-ft. unit, then I reduce the unit, but maintain the foot-weight. My reason for this is that the lighter the sample the greater the care that must

I agreed with Mr. Parsons in his desire to utilize the law of averages to a maximum, and I preferred hand sampling to mill-tests where a choice of only one or the other method had to be made. I took the position that utilizing the law of averages to a maximum extent would, however, fail to disclose a sampling-error latent in the ore. Close sampling is valuable; in fact, it is necessary in a mine where the value of the ore fluctuates greatly, but it will not detect a latent error, which, when it exists, is latent in each sample without reference to the number taken. Latent errors in sampling can be detected only by actually treating the ore. In the 'Mining Magazine' of February 1915, I contributed an article entitled, 'Latent Errors in Mine-Sampling'. I tabulated various classes of error under the following heads:

- (1) Mines where the average metal-value is mechanically reduced, but where the unaccounted metal may be subsequently recovered.
- (2) Mines where there exists an unrecoverable loss.
- (3) Mines where sampling indicates a fictitiously high value.
- (4) Mines where sampling results in an incorrect sub-normal value, conclusive proof being afforded by subsequent commercial results.
- (5) Mines where sampling is of no use.

No. 3, 4, and 5 are latent errors. Close sampling in these cases only duplicates or reproduces the error. The other numbers refer to mechanical errors introduced in the removal of the ore. I will endeavor to show that a latent error cannot be estimated, but can only be arrived at by comparison between hand-sampling and mill-feed, whereas a mechanical error can be approximated by the examining engineer, by using the experience obtained in mining similar deposits.

In dealing with latent errors I enlarged upon the subject in the 'Mining Magazine' article as follows: In respect of No. 3, I stated: "Where the metallic contents of ores are in sulphide form the sulphides are frequently more friable than the gangue. In consequence, the samples will contain an abnormal proportion of high-grade 'metallies'. Discrepancies of this class are more usual in copper and other base-metal mines, but in the case of gold and silver ores, where the metal is enclosed in a vehicle of friable sulphide, this error should be very carefully

be exercised in its removal. In the cutting of a light sample there is always the temptation to remove obtruding pieces that come away easily. In small examinations, where the engineer can devote personal attention to cutting samples, light sampling is preferable; but in large examinations I depend on heavy sampling and excite the crews to cut even channels as evidence of their good work. In large examinations, where pneumatic channelers are used, light sampling is impossible, irrespective of its other failings.

considered, as it may result in an estimation out of all proportion to subsequent results."

Enlarging upon No. 4, I stated: "Where there are two sulphides in the same ore, one hard and dense and the other soft and friable, the latter will break more easily in sampling, and will, therefore, be abnormally represented in the valuation. If the major richness is in the hard sulphides the inference is liable to be unfair to the property and the reverse."

Enlarging upon No. 5, I stated: "There is a class of mine where the valuable minerals occur in bunches. Under such conditions no confidence can be placed in an assay-map, even although an unusually close sampling-interval may have been employed. A level on a certain horizon may pierce a certain number of enrichments which would be represented on the sampling record. Had the horizon of the level been, however, 30 ft. higher or lower, the number of enrichments pierced in the latter case would be out of all proportion to the former. In a mine of this type an attempt to sample blocked-out ore would be absurd. The nature of the ore occurrence would demand a veritable network of levels and raises so adjacent to each other that all hope of a commercial undertaking would be obliterated by the development charge per ton. Innumerable cases exist where an assay-plan would show the majority of samples as unprofitable, yet, the commercial result has afforded conclusive proof to the contrary. This class is not composed only of precious-metal mines. The base-metal mines of Missouri and the copper mines of Lake Superior are analogous. The only method of reliable valuation in a deposit of this type would be based on the authentic record of the past yield, in combination with selected representative shipments of the remaining ore."

In view of the foregoing I felt therefore that exponents of either method were in error in the general premise in so definitely taking sides for the mill-test on the one hand or hand-sampling on the other. I advocated that there were advantages in either method, and in order to sample a large low-grade deposit so that the true gross or stopping value of the ore could be estimated, a combination method would have to be employed that would contain the advantages of hand-sampling and also of mill-tests.

At that time I explained a 'combination' method that I had devised for sampling a large low-grade gold deposit in Central America. In this case careful hand-sampling indicated an enormous tonnage of ore that would yield a profit of \$1 per ton. The 'combination' method devised by me, however, disclosed a latent sampling-error of 40 cents per ton. This was 40% of the operating profit as based upon hand-sampling.

The 'combination' method was described in detail in the article from which I have quoted; broadly, it consisted in a large number of small mill-tests spread over the ore deposit; these served to correct the hand-sampling of the spaces intervening between the mill-tests by a factor obtained by successive sampling of the faces of the small stopes as the ore was removed with the recovery

plus tailing loss. The property, therefore, was sampled by hand, but, as stated, each mill-test performed the function of a 'sampling-error indicator' and controlled the hand-sampling of an area or zone surrounding each small mill-test. In this way the entire area was split into mill-test zones. The distance between one mill-test and its neighbor was not uniform. It was controlled by the average of the degree of error between one mill-test and its neighbor; in other words, if there was not a wide discrepancy in the degree of error between one mill-test and its neighbor, the average of the two factors was taken to control the hand-sampling of the intervening space. If there was a wide discrepancy the zone was subdivided by introducing a mill-test in the centre, and so on, until the degree of error became sufficiently uniform to be employed as a factor to correct the sampling by hand.

I emphasize that the size of the area to be controlled by two mill-tests is not governed by the degree of error obtained, but by the fluctuation of the degree. In a contribution by H. R. Sleeman, he indicated that he would advocate the use of the combination method in a case where the mill-test indicated an error up to 8 or 10%. As to this, I believe I have made it clear that the degree of error has little bearing on whether or not the combination method should be employed. What is vital is the uniformity of the error over large areas without reference to how much the error may be. This phase of the subject was ably discussed by R. E. Raymond in his contribution dated November 3, 1917, where he says:

"On thinking over the most practical method of deciding upon the size of the zone I would suggest, if it is intended to put in a 'chain' of mill-tests, that the variation of the sampling-error between one mill-test and its neighbor should be the governing factor on the size of the zone. Whether the sampling-error is large or small should not be a factor in this decision. A mine indicating a fairly uniform sampling-error of 40% could stand much larger zones to each mill-test than a mine where the sampling-error fluctuated from zero to 20%."

In the actual case cited, in Central America, the 'combination' method was successfully employed and prevented a heavy financial loss. The latent sampling-error of 40% was, however, comparatively uniform.

The questions asked by other engineers may be outlined as follows:

A. As the intention is to correct hand-sampling by the factors disclosed by the bulk-sample, would I add a factor to hand-sampling when the bulk-sample showed a greater metal content than indicated by hand-sampling?

B. To describe in detail the means of obtaining the sampling-error from the bulk-sample.

C. A description of the method of arriving at the size of the zone that is to be governed by a mill-test.

D. Would not the application of this method to mines containing secondary enrichment be attended with unusual difficulty?

Answering question A: I have examined mines that milled or shipped better than hand-sampling would in-

dicate. I believe I have answered this question in my reference to my old article on latent errors that appeared in the 'Mining Magazine', under tabulations No. 4 and 5.

In answering question *B*: As to how to obtain the sampling-factor from the bulk-test, I will describe how this was done in the actual case in Central America. The width of the vein was about 30 ft. Holes one foot deep were put in the back of the levels about 18 in. apart, in five rows from wall to wall about 2½ ft. apart. Before the holes were drilled, five channels were cut from wall to wall 2½ ft. between each channel. After the round was fired, five new channels were sampled, when another

stope should not be less than one-third the width of the vein. This relation of the quantity stoped to the width of the vein should not be taken as a ratio to be applied to narrower veins and generally dissimilar deposits.

Two features may be mentioned as having been disclosed by this experience: (1) That it was found unnecessary to make 50 separate assays to represent the hand-sampling of the stope. It was found, by carefully mixing and cutting down the samples from each channel by means of a Jones sampler to pulps of similar weight, that the assay of the resulting pulp was sufficiently close for practical purposes to the average of 50 separate

series of one-foot holes was put in, and so on. In this way a small stope was carried up for the entire width of the vein. Care was taken not to drill the holes more than one foot deep, because it was important to have as many hand-samples from the re-channeling of the back of the stope as possible. The law of averages was employed to a maximum by this means; namely, five separate channels 2½ ft. apart cut after every round which broke not more than one foot in vertical height. The back of the stope was carried up about 10 ft. In this way about 200 tons of ore was obtained, which was represented by 50 assay-pulps. The difference between the average of the 50 assays and the mill-recovery, plus tailing loss, gave the sampling-error. If the vein had been narrower, a smaller mill-test would have been employed. After the sampling-error is obtained, there is little gain in continuing to stope more ore from the same place. I felt in the case under review that the length and height of the mill-test

assays. If this 'short cut', however, is employed it is absolutely necessary that the sampling crew must be sufficiently skilled in cutting down to finish with pulps of similar weight. (2) If I were to sample another large low-grade ore deposit, I would not use a mill to obtain the mill-test. The same result can be obtained by employing a bulk-sampler, as used at smelters. In the Central American case I had to use the equipment at my disposal, namely, a small mill; and in order to get the mill-feed it was necessary to add the recovery to the tailing loss, the sum of which is automatically and more accurately obtained by a bulk-sampler.

In respect to questions *C* and *D*, dealing with the means of determining the size of a mill-test zone and the influence of secondary enrichment in the application of this method of sampling, I will submit an ideal longitudinal projection. Mr. Sleeman referred to the influence of secondary enrichment. While I do not see a fundamental

reason, why secondary enrichment should vitiate this method of sampling. I will, however, state that this method was originally devised for sampling low-grade gold deposits. In my experience I have not met with any examples of secondary enrichment in gold deposits; and I doubt if they exist. There are a large number of gold deposits that owe their profitable nature to differential enrichment, but not to secondary enrichment. The latter is the migration and re-precipitation of sulphides on a metal base. Differential enrichment as found in gold mines is the leaching out of solubles, leaving the original metallic content differentially enriched.*

In dealing, however, with copper or other base-metal cases, where true secondary enrichment is in existence as represented by the diagram of the ideal case, it will be noted that the fluctuation in the sampling-error would adjust itself automatically. On level No. 1, it is assumed that because secondary enrichment is below this level there is a uniform degree of error, and therefore the mill-tests are put in at regular intervals, the value of the ore-body being obtained by hand-sampling, corrected by the average of the error obtained by the mill-tests. On level No. 2, secondary enrichment begins to appear at the point *A*. The mill-test put in at *B*, the usual unit distance from mill-test *C*, discloses a wide fluctuation in the degree of error, with the result that the distance is split in two, and mill-test *D* is made. While a large fluctuation may be observed between *D* and *C*, it is reasonable to expect that *D* and *B* will be more or less the same, as the ore is obtained in both cases from the secondary zone. If, however, a considerable discrepancy should exist, there is no reason why the distance should not be subdivided. The same method could be pursued on the third level where it intersects the sulphide zone.

This diagram should illustrate the point made by me in my former writing on the subject, that the 'combination' method is not dependent, as Mr. Sleeman claims, on the smallness of the sampling-error, but on the uniformity of the degree of sampling-error. If the average of the error from *H* to *K* was 5%, but comparatively uniform between mill-tests, say, 300 to 400 ft. apart, I claim that an error so obtained could be safely used to correct hand-sampling over this distance. If the error *K* to *M* was found to average 30% or more, as long as the error in the secondary zone did not fluctuate sufficiently from place to place to require mill-tests at such close intervals, as would make the method of sampling financially prohibitive, then there is no reason why the error obtained by the mill-tests should not control the hand-sampling between *K* and *M*. As long as *H* to *K* has a uniform error and *K* to *M* has a uniform error, I see no reason why the 'combination' method should not be successfully applied to base metal deposits as well as gold deposits.

Mr. Raymond stated that, had the 'combination' method

been applied to the Alaska Gastineau the loss of about \$15,000,000 would have been prevented. I note that Mr. Pierce states that at all events a large part of the loss would have been saved. As to this, I cannot say. I would make myself ridiculous if I made such a statement about a property with which I am not thoroughly familiar. I have, however, used the 'combination' method in the actual case presented, and thereby avoided a heavy financial loss. I am also familiar with other important mining enterprises where this method could have been successfully applied. As we grow older we realize it is upon the 'honest failures' of ourselves and compeers that a large part of progress is based.

WULFENITE is one of the two ores of molybdenum found in commercial deposits in the United States. The other, molybdenite occurs more frequently and for that reason has been given greater consideration by those working on methods of treatment. J. P. Bonardi has, however, done some experimental work, the outcome of which he summarizes as follows: The results found with the experimental Wilfley table indicate that wulfenite can be concentrated from a barite gangue with very promising results, since on the small laboratory machine used, a recovery of between 60 and 70% of the molybdenum could be effected by passing the material only once over the table. It must be remembered also that a recovery had previously been made on the original milled ore of over 60%, so that the additional increase obtained from the middling material, when ground through 80-mesh and with no further classification, gives a total recovery of over 85%. This recovery on material that had received no special classification, outside of grinding, emphasizes further the adaptability of wet concentration methods to wulfenite ores, even with such high specific gravity gangue as barite. By a slight rearrangement of the mill circuit, wulfenite should be as readily separated from barite as from gangues of a lower specific gravity.

PHOSPHATE DEPOSITS have been discovered in the eastern part of Holland, at a place called Ootmarsum, in the Twente district. About 30 tons of 15 to 20% phosphate is being produced each day, and is being sold locally at prices corresponding to the prices of imported phosphate. The stratum ranges from 7 in. to 3 ft. in thickness, but on account of the fact that it is not continuous the work of extracting the rock is very expensive. In some places the stratum is on the surface; in others it is as much as 25 ft. beneath the surface.

A \$15,000,000 national mining corporation has just been formed by the leading British mining finance companies, in co-operation with British capital, to develop mining properties on a large scale in different parts of the world, says a recent bulletin of the American Chamber of Commerce in London. The new corporation is expected to be a British parallel of such American organizations as the American Smelting & Refining Co. and the United States Metals Co.

*While it is not in direct line to this subject, it may be well to mention that a large number of gold mines owe their origin to differential enrichment and the falling off in gold content on leaving the superficial hydrated surface is responsible for the huge mortality of gold deposits in depth.

Valuation of Oil Properties for Federal Taxation

The Price of Californian Crude Oil After March 1, 1913, to be Used in Valuing Oil Properties as of That Date

INTRODUCTION. A committee, representing a number of the larger oil companies in California, met in San Francisco on November 12, 1919, for the purpose of discussing the depletion deductions to be allowed in computing the Federal income-taxes under the Internal Revenue Act of 1918. It was the general sense of the committee that a system based on sound engineering principles should be formulated for estimating the value of oil properties, so that better and more uniform results might be obtained by the various companies in filing their returns with the Bureau of Internal Revenue. A sub-committee consisting of five petroleum engineers was thereupon appointed to collect information and draft a report; the committee consisted of G. C. Gester, Carl H. Beal, J. H. G. Wolf, E. G. Gaylord, and E. D. Nolan. This report is the work of that committee.

GENERAL STATEMENT OF PROBLEM. The recent manual of the Treasury Department compiled for the administration of the income and excess-profits tax-laws for 1918 gives the method of estimating future oil-reserves by the latest engineering principles, but no definite method was established for fixing the value of the oil in the lands in question, except that the value should be as of March 1, 1913. It seems to have been assumed that the value of oil-lands would be fixed by sales in the open market of similar and adjoining properties. This method is absolutely useless in the Californian oil-fields for three reasons:

(1) Sale-prices, to be of any value, according to the Treasury Department, must represent transactions between "a willing buyer and a free seller". This condition could not be fulfilled in 1913, because of the great depression, which resulted in 'forced' sales only, and

(2) Sales of large and successful properties were and are rare, and

(3) The productiveness of adjoining tracts varies so greatly that the selling-price of one tract can be equitably applied only with great difficulty as the standard of value for another tract.

In addition, production seemed to have nearly reached its maximum, while the demand was steadily increasing, so that obviously a higher price would prevail in the future. Therefore, if, for the March 1, 1913, valuation for the price at that time were used for applying to future production, improper results would be obtained.

PRESENT-VALUE METHOD. The present-value method for estimating the value of oil-lands, and mining properties in general, is recognized as the latest and soundest engineering method of appraising such properties. It

has been thoroughly discussed by Herbert C. Hoover in 'Principles of Mining' and by John R. Finlay in the 'Cost of Mining'. There is every reason to believe that the Treasury Department will accept values of oil lands as fixed by this method, provided sufficient data are at hand to determine the essential factors with reasonable trustworthiness.

L. C. Graton, Valuation Engineer of the Internal Revenue Department, in an article entitled 'Federal Taxation of Mines' in the November bulletin of the American Institute of Mining & Metallurgical Engineers,* discusses this problem, and shows this to be the generally accepted method among engineers for arriving at the value of mines, and, likewise, of oil properties. This method is also the method recommended to the Treasury Department in a report prepared in October 1919 by a committee of mining engineers, representing the American Institute of Mining & Metallurgical Engineers, who had been in convention in Chicago in September 1919, and who were invited to Washington by officials of the Treasury Department to draw up suggestions for re-writing the departmental regulations governing the application of the income-tax law to the mining industry.

The essential factor to be determined, in applying the present-value method, is the future selling-price of the oil, and it is with this factor in determining oil-land values that the following report deals. Mr. Graton emphasizes the fact that all available data should be used in determining the future selling-price; he states "that the trend in such cases, rather than the average, is important. Yet it must be ascertained if the trend is in itself but a part of a minor fluctuation; that is, the component of a greater trend."

GENERAL CONDITION OF THE OIL INDUSTRY IN 1913. Production in California in 1913 had been rapidly increasing for several years, but evidence was at hand to show that this production was about to reach its apex and would, thereafter, begin to decline. The statistics available, to one making estimates of value as of March 1, 1913, would indicate that consumption during several years prior to 1913 was gradually approaching production, and in all probability, stocks must soon thereafter be drawn upon, in order to supply the demand if the same rate of consumption continued.

Several authorities may be quoted in support of the above statement. Mark L. Roqua, late oil administrator

*See also 'M. & S. P.', October 11 and 18, 1919

for the Federal Government, in an address delivered before the Mining Association, University of California, Berkeley, in November 1912, on the 'Oil Resources of California', said:

"It is not possible that this increase can continue in any such ratio over any long period. There is reason to believe that California can find a market for 80,000,000 bbl. annually within two years and 100,000,000 bbl. within five years."

Ralph Arnold, late chief of the oil and gas section, Bureau of Internal Revenue, made the following statement in the bulletin of the American Institute of Mining Engineers, of March 1914:

"As a concluding statement concerning production, it is the senior author's belief that the total yield of California for any one year will never go much, if any, over 100,000,000 bbl. and that the time will come within the next year or two when the maximum production will be reached, after which the curve of production will be a descending one. Such has been the history of all of the older fields in this country and such is the logical result to be expected in California. With the increasing uses and markets for oil resulting in a constantly increasing consumption, it is obvious that the price of oil will go up rapidly the minute the general public realizes that the reserves are being drawn upon to meet the demand."

MARKET. The Californian oil-fields supply a region that forms an economic province within itself, because it is far removed from any other competing oil-fields. The scope of its market includes all of the Pacific Coast of North and South America, the Hawaiian Islands, China, and Japan. This whole region was rapidly developing prior to and during the year 1913, and the Pacific Coast section of the United States was growing more rapidly in population and the industries were expanding much more rapidly than the remainder of the United States. Furthermore, this region is marked by the scarcity of its coal resources, and the growing industries were and are largely dependent upon Californian oil for their supply of fuel.

Mr. Requa stated in November, 1912, in regard to this market:

"With the completion of the Panama Canal, provided a satisfactory supply can be obtained on the Atlantic seaboard which there is reason to believe is not improbable, steamers between New York and San Francisco and possibly European ports will use oil as fuel. The present market comprehends a territory from Alaska to Chile and inland as far east as Carlin (Nevada), El Paso (Texas), and Albuquerque (New Mexico). Within this area there is yet much room for expansion and if we add to this the possibilities open to this by the completion of the Panama Canal, we have a market of enormous potentialities."

David T. Day, of the U. S. Geological Survey, emphasizes the importance of petroleum to the Pacific Coast in the 'Production of Petroleum in 1912', as follows:

"The production of California will undoubtedly become a more significant element in the general petroleum industry with the opening of the Panama Canal until at least the consumption in California outstrips production. It is not improbable that the flow of fuel-oil through the pipe-line alongside the Panama Canal may eventually

be reversed because fuel-oil is essential to the industrial development of the West Coast."

The above statements show conclusively that the enormous possibilities of the market for Californian oil and the necessity of the supply of fuel-oil on the Pacific Coast were clearly recognized in 1912 and 1913.

TREND OF FUTURE PRICE. The price of any mineral is limited on the one side by the lowest cost of production of any operating property, and on the other side by the cost of competitive materials. If no oil can be produced at a profit very soon none will be mined. In the year 1913 oil was selling at a base price of 35c. per barrel in California. At that time, the cost of production from numerous properties was at least this much per barrel and possibly more. It is evident that prices in 1913 were at a minimum as a result of flush production, which began with the year 1910 in the Midway field. The only possible change in prices would necessarily be upward.

The other limit, providing the market could be expanded sufficiently to absorb production, and this we have already shown was quite probable, would be the cost of competitive materials. We have already commented on the scarcity of coal on the Pacific Coast.

In November, 1912, Mr. Requa made the following comment on the coal situation in California:

"The west coast of North America, Central and South America, is poorly supplied with coal deposits. Aside from the deposits in Washington, British Columbia, and undeveloped resources of Alaska and Peru, there is no available fuel of satisfactory quality. The coal that is produced does not compare with the best Eastern, Welsh, or Australian coals and the cost is materially higher. Herein lies the reason of the great success of and the demand for Californian oil."

In the same address, Mr. Requa gives the fuel-ratio between steam-coal and Californian oil as one ton of coal to three and one-half barrels of oil.

In 1913 steam-coal in shipload lots sold for \$7 per ton in San Francisco. This would indicate a value of \$2 per barrel for Californian oil for fuel purposes only.

In bulletin No. 365 of the U. S. Geological Survey, the fuel-ratio between the coal of Puget Sound, which is the source of the greatest amount of coal used on the Pacific Coast, is given as one ton of coal to three barrels of oil. This ratio indicates a value of \$2.33 per barrel for Californian oil.

Emphasis must be put on the fuel-value of oil because the bulk of the Californian production is fuel stock. Quoting again from Mr. Requa, he makes the statement that fuel consumption of the Pacific Coast had increased 70% over a five-year period preceding, but coal consumption had remained approximately the same.

In Bulletin 69 of the California State Mining Bureau, written in 1914, there is the following statement:

"The maximum price at which oil can sell is not so easily determined as there are many influences bearing upon it. In general, fuel-oil cannot sell for a greater price than that at which the consumer can profit by turning to some other source of power, such as coal, electricity, or wood. An instance, merely for an illustration as the figures may not be exact, is that the maximum cost

at San Francisco could not be greater than that of coal which has usually sold wholesale for from \$6 to \$8 per ton, but has been estimated as possible at \$3.50. Tests have shown three and one-half barrels of oil to be equal in heating-value to a ton of coal. Therefore, the maximum price of fuel-oil at San Francisco should be about \$1, or possibly \$2, depending on the price of coal. As a matter of fact, it has usually sold at from 60 to 70 cents."

W. W. Orentt, chief geologist for the Union Oil Co., in a private report dated April 20, 1912, stated:

"The demand for Californian oil can be enlarged to almost any reasonable amount by extending its markets. The actual consumption of Californian crude oil increased tenfold during the period of 1900 to 1910. This was due very largely to increased consumption in the Pacific Coast States. This local market is still growing rapidly, owing to the great development of the West. There are also extensive markets in Hawaii, Japan, Alaska, and South America, and the completion of the Panama Canal will open the markets of the Eastern United States and Europe. At the Canal the paths of the merchant marine of the world will converge, and there it will 'fuel-oil' its ships. Oil and transportation only are necessary to be able to supply these markets. At its present rate of consumption, California has a supply of crude oil sufficient to last 50 years. The industry does not now have enough transportation, but it can and will be supplied. When this is done the field of consumption will be enlarged and the demand for oil will be increased; therefore, the market-price must advance. In comparison with coal, fuel-oil should be worth \$1 per barrel at the wells of production within the next few years, and for refining oils a still higher price will, in all probability, obtain for the same period.

"The average price figured in the following estimate of production, receipts, and expenditures, is from 50 to 75 cents per barrel, but I believe that the average price that will actually be received for the next twenty or twenty-five years will be much higher."

The value of Californian oil in fuel alone represented at least \$2 per barrel in 1913 and it was the opinion of the leading operators and petroleum engineers that the price of oil would soon rise to a much higher figure than that obtained in 1913, both on account of the large undeveloped market and the necessity of oil for fuel.

Regard must also be taken of the fact, as the records show, that when once the price turns upward the trend is not checked until the conditions that brought about the movement change; so long as demand exceeds supply the price current is upward. The records show that it is not sufficient merely for the supply to equal the demand, it must exceed demand before the trend is halted. This is

because at no time in history has the market failed to absorb new production when once the facilities for distribution were established. Crude petroleum as a commodity differs in this way from almost every other staple of commerce; its position in industry and economics is therefore individual, and its problems must be so treated. The substance is unregenerative in nature, hence the quantity available is fixed, while the demand may be practically unlimited.

CALIFORNIAN PRODUCTION NEAR ITS APEX. A detailed study has been made of the entire production of the various fields in California. Curves of the production of these fields are shown on Plate I. From these curves it is evident that the production in all but two of the fields in

California had already reached its peak and was on a permanent decline. The two fields that were as yet increasing in their production were the Midway and the Whittier-Fullerton.

The daily output per well in the Midway field began to decline in the spring of 1911, but the total production continued to increase because of the great number of wells that were constantly being drilled. With a rapid decline in the average production per well per day, it may therefore be concluded that while the crest of production in the Midway field had not been reached in 1913, the peak production of the field would be reached within a short time.

The Whittier-Fullerton field was still increasing in production and the average production per well per day was also increasing. It was therefore logical to assume

that the crest of the production in that field was indefinite. In the year 1913 the Whittier-Fullerton field did not bear the relative importance to the total production of California that it now does, and there was no reason to believe that its increase would make up for the declines of all the remaining fields, and an engineer at that date would be justified in assuming that the Californian production was about to pass its crest and start on a decline.

Mr. Arnold has stated that 100,000,000 bbl. would be the approximate maximum production obtained in any one year in the State of California.[†]

CONSUMPTION APPROACHING PRODUCTION. Statistics of the Government bureaus show that several years prior to 1912 a considerable gap existed between consumption and production, and that at the beginning of 1912 production still exceeded consumption by a considerable margin. The excess, however, diminished rapidly during that year and at the beginning of 1913 consumption practically equalled production. On March 1, 1913, there was so little difference between consumption and production that the field-price of crude oil increased five cents per barrel. In the fall of 1913, consumption exceeded production.

Even though it is not established that production in California had reached its apex in 1913, the rise in price in the future would be as certain, provided consumption exceeded production.

The Standard Oil bulletin in June, 1914, stated as follows:

"From 1901 to 1906 there was a constant over-supply and the average prices consistently dropped. From 1906 to 1909 storage was reduced, the reduction reflecting an increased demand, and values moved up correspondingly. Nineteen-ten was a gusher period in the Midway district and storage increased rapidly accompanied by decreased prices. This condition continued until 1912, when the demand had substantially approached the supply and the price had again started on an upward trend."

It must be remembered that at the beginning of 1913 no engineer could have foretold the depression that was to come in 1915 as a result of the world war.

An article in the 'Mining and Scientific Press' for October 11, 1913, is worthy of consideration.[‡] Curves are therein presented to show the rate at which consumption was approaching production during the years 1911 and 1912. These curves show consumption equaling production during the first part of 1913. When consumption equalled and threatened to exceed production, stock would have to be drawn upon to meet the demand. The law of supply and demand would then necessitate an increase in the price of crude oil. Furthermore, as the production of crude oil was approaching its peak and as the markets for crude oil from this State were rapidly increasing, then in the year 1913 an engineer would be justified in believing that future years would see a constantly increasing price for oil.

[†]'Geology and Technology of California Oil-Fields', Ralph Arnold and V. R. Garfield, A. I. M. E., March 1914.

[‡]'California Oil Production for 1913', by J. H. G. Wolf.

PETROLEUM RESOURCES. Petroleum is unregenerated in nature and the supplies of it are therefore limited and exhaustible. It was recognized by leading engineers long before 1913 that the resources of California were limited. Mr. Requa, in the paper already quoted, discusses the future production of the State and makes the statement that no important extensions of the present fields may be expected north of Coalinga or south of Fullerton.

Dr. Day, in bulletin No. 394 of the U. S. Geological Survey, shows that California was believed to be the only State on the Pacific Coast that possessed commercial deposits of petroleum.

Both Mr. Arnold and Dr. Day made estimates of the probable future production of petroleum in California. The former's estimate, made in 1908, gave a minimum of 5,000,000,000 and a maximum of 8,500,000,000 bbl. Mr. Arnold estimated in 1915 that only 2,300,000,000 bbl. of extractible oil remained in the ground. This, when compared with the annual production of approximately 100,000,000 bbl., is deeply significant.

As it was recognized that the resources of petroleum on this Coast were comparatively limited and exhaustible, and as petroleum is absolutely necessary to modern civilization, it follows that all land from which oil might be extracted at any time in the future, had a potential or prospective value in 1913.

SUMMARY. Conditions in California, affecting the future price of oil, of which an engineer might have been expected to have knowledge in 1913, may be summarized as follows:

California controlled a region that was an economic province in itself, consisting of all the territory contiguous to the Pacific Ocean. It was a region that was rapidly expanding, and in which many new industries, largely dependent upon the oil for their fuel-supply, were being developed.

The period immediately preceding 1913 was one of flush production, with a rapid increase in the total production of the State.

The selling-price of oil in 1913 was below the average cost of production, and therefore, represented a minimum price. The price of coal, which was the chief competitor of Californian oil, would indicate a value of at least \$2 per barrel for oil in San Francisco.

The study of the production from the various fields in the State would indicate that the production of the State was nearing its apex. This, also, was the opinion of leading engineers including Mr. Arnold, late head of the oil and gas section, U. S. Bureau of Internal Revenue.

The proportion of high-grade refining oil was steadily increasing and this would in itself indicate a greater value for the State's production in the future.

Consumption, which had lagged behind production for several years prior to 1913, approached, and even exceeded, production during that year. There was every indication that stocks would shortly have to be drawn upon to a considerable extent to meet the increasing demand.

In view of the above facts it seems logical to assume

that an engineer with the viewpoint of 1913 would expect an ever-increasing price of oil in the future.

FORECAST FROM RESULTS IN OTHER FIELDS. The preceding argument establishes the fact that a rise in the price of oil after March 1, 1913, was imminent; we now turn to the history of price and production in other fields of the United States for confirmatory evidence.

The real problem was to forecast in a rational way, and in accordance with engineering and economic principles, what this expected increase might be from year to year in the future. A study was made of the results of the law of supply and demand in other important oil-fields of the United States where the course of free prices over a number of years was available from Government statistics.

The annual production and average annual price from the following major fields in the United States were plotted from data published by the U. S. Geological Survey for as many years as it was possible to obtain information:

1. Appalachian field, comprising south-western New York, western Pennsylvania, north-western West Virginia, and south-eastern Ohio (Plate II).

2. Lima-Indiana field, comprising western Ohio and eastern Indiana (Plate III).

3. Illinois field, lying in the south-eastern part of Illinois (Plate IV).

4. Gulf Coast field, lying in the Gulf coastal plain (Plate V).

The Appalachian curves (Plate II) show that the peak of production, which corresponds closely to the time that prices began to increase, was in 1891. The trend in prices from that time onward was consistently upward. An average line was drawn through the price-curve showing the upward trend of prices as far as the year 1912, no subsequent information being used. The average annual percentage of increase in price was then computed. The same statistics were determined from the price-curves representing the remaining major fields. The results from the four fields may be tabulated as follows:

Field	Average annual increase in price, %	Years over which price increase was computed
Appalachian	11.3	1891-1912
Lima-Indiana	9.8	1906-1912
Illinois	20.9	1910-1912
Gulf Coast	7.4	1905-1912

It is to be regretted that statistics giving shipments or consumption were not available. Although it follows necessarily that when production started permanently to decline, the consumption caught up with the production and soon exceeded it, the curves showing the actual consumption would bring out more clearly the action of the law of supply and demand.

Storage statistics are available from 'Mineral Resources' for the year 1907 onward, and these have been plotted on the several curves. They serve as excellent substitutes for the consumption curves, because they indicate clearly the time when consumption exceeded production and it was necessary to draw upon stored oil to meet the demand. It will be noted that the price began

to rise immediately, and the trend, in general, was upward for the remainder of the life of the field.

CONCLUSIONS. A full consideration of all the evidence available, both as to the general conditions in California and the history of the price and production statistics of the older oil-fields of the United States, warrants the following conclusions:

1. The rate of increase in the price of crude oil at the well prior to the year 1913 for four major fields in the United States, when once consumption passed production, was found to average about 12.3%. The certainty with which the course of prices changed definitely upward the moment consumption passed production gives to this fact a weight and importance approaching that of a fundamental principle of the oil industry, and proves the inexorable working of the law of supply and demand.

2. Consumption in California had equalled production in the latter part of 1912; and petroleum engineers and operators generally were expecting an increase in the price of oil in the immediate future.

3. Industries were expanding in the territories dependent upon California for their supply of oil more rapidly than in the four fields that furnished our precedent for determining the probable course of prices. Foreign markets in South America, Asia, the Hawaiian Islands, and the domestic Coast were opening and becoming absolutely dependent upon the Californian crude oil as their source of fuel.

4. After considering the facts as nearly as possible from the 1913 viewpoint and taking into consideration the opinions expressed publicly and privately at that time by petroleum engineers and operators, we are convinced that the price of Californian oil from 1913 onward could reasonably have been expected to increase consistently, for the supply had already been equalled by the demand. Because of the relationship between supply and demand at that time, prices could have been expected to increase at least as rapidly, and very likely more rapidly, than they had in other fields in previous years. In fact, the price increase could have been expected to be as rapid as that for Illinois (about 21%), for this State had to depend absolutely on its own supply, whereas Illinois lies within the markets of other large and only partly exhausted fields.

5. The schedule of prices in the accompanying table is therefore proposed for adoption by engineers and oil companies in making appraisals of oil properties as of March 1, 1913. The principle involved should be applied likewise to appraisals made as of any date subsequent to March 1, 1913. The prices after 1913 are based on an average annual increase of 15% of the base price paid on March 1, 1913, with the exception of 14°B. to 21°B. oil from the San Joaquin valley, no increase being given for 1913. An average annual increase of 17% was used for these grades as produced in the San Joaquin valley, because of the difference in the 1913 price paid for these oils and those of the next higher gravities, namely, 35c. for the fuel grades and 50c. per barrel for

the oil between 21°B. and 23.9°B. To increase the price of the former at the same rate as that of the latter would make an improper and unjustified difference in the prices to be received for those grades in subsequent years. The greater rate of increase for the fuel grade is further justified by the fact that the stocks of fuel-oil were decreasing at this time in spite of material additions to the supply by the residuums of the refining grade. The following table and statement, published in the Standard Oil bulletin of June 1914, shows this decrease nicely:

Six months ending	Barrels (42 gal.)	
	Under 20° B.	Over 20° B.
December 31, 1911	28,052,191	15,325,631
June 30, 1912	26,437,746	17,233,966
December 31, 1912	25,500,954	20,875,743
June 30, 1913	25,070,035	22,151,861
December 31, 1913	23,602,839	27,042,569
		Total
		43,377,822
		43,697,742
		46,376,697
		47,231,836
		50,645,348

"It will be seen that from the end of 1911 to the end of 1913 the fuel-oil for a six months period declined 4,450,000 bbl. while the production of light refinable crudes increased 11,700,000 bbl. It may be said further that the average gravity of the light crudes two years ago was but little higher than 21° gravity, while the gravity is now above 25°. The figures here offered should suffice to show that the economic law of supply and demand is the certain and immutable factor in the regulation of prices."

That the proposed prices are reasonable and conservative may easily be seen by referring to the actual price of crude oil in California today. For instance, in the table, the price in 1919 for the fuel grade is 70c., whereas that actually paid is \$1.23 per barrel at the well, and this price prevailed as early as May 1918. It should be remembered that these prices are those that we feel could reasonably have been expected by oil-operators and appraisers on March 1, 1913. The European war and the resulting extraordinary stimulation in the demand for, and price of, petroleum could not have been foreseen by anyone. Furthermore, no one knew at that time that the purchasing power of the dollar, as compared with the pre-war period, would decline to approximately 60c., and that all commodities, as a result, would have increased greatly in price.

It will be noted that no price has been estimated for years subsequent to 1924. These estimates have been omitted only because of expedience. In our opinion, appraisers, in estimating the price of oil after 1924 should retain the same percentages upon which the table is based, that is, an average annual increase of 17% over the 1913 base price for fuel-oil, and 15% over the base price paid in 1913 for the oils of higher gravity. This rate of increase is regarded as the minimum, and should be retained up to the point when the price will be affected by the importation of fuel-oil from Mexico and by the use of hydro-electric power and of coal. Although no

Table Showing Market Price for Different Grades of Crude Oil at the Well in California on March 1, 1913, and the Prices that Reasonably Might Have Been Expected for the Same Grades of Oil in Eleven Subsequent Years.

evidence is available that will indicate at just what time in the price-course these three sources of power will affect the price of oil, nevertheless, it is certain that at some time in the future these three elements will gradually have their effect upon the rate at which the price of fuel-oil will advance. This rate of increase will gradually decrease until a balance has been struck. The upper limit of the price of fuel-oil has been taken at \$2.50; and

per barrel at the well has been taken as the price when these three elements will begin to affect price history. It is therefore recommended that a 17% average annual increase be used for fuel-oil until it has reached the price of \$2 per barrel, and that thereafter the annual increase will be 16%, 15%, 14%, 13%, 12%, 11%, 10%, 9%, 8%, 7%, 6%, 5%, 4%, 3%, 2%, and 1%.

In the case of the refining-oil, \$4.50 has been assumed as the upper limit, but \$4 has been taken as the point at which the prohibitive price of the products obtained from refining-oil will gradually lessen the demand. The 15% average annual increase over the 1913 price should therefore be used until oil has reached approximately \$4 per barrel, and the rate thereafter decreased gradually until \$4.50 is reached. The estimate of \$4.50 per barrel at the well as the upper limit at which refining oil will sell is justified by the rapid increasing demand for gasoline in the automotive industry.

It is conceded that the estimates of price for many years in advance cannot be determined with accuracy, but if the present value method of appraising oil properties is to be used, it is necessary to make some estimate of the gross price received for the product. The appraiser, however, is safeguarded to a certain extent by the comparatively small present-value of profits derived from oil properties ten or twenty years in the future. For example, a well producing in 1913, as a general rule, will have obtained most of its profit within ten years. The annual profit from that time onward, even though the price of oil is much higher than formerly, will be of comparatively small importance when discounted back to 1913.

As these conclusions and the premises upon which they are based have been reviewed by many engineers and heads of oil companies thoroughly conversant with Californian conditions in 1912 and 1913, and at subsequent dates, the conclusions may be taken as representing the consensus of opinion of those engaged in the oil industry of California.

Recent changes in the regulations for Federal taxation governing re-valuation of oil properties subsequent to discovery have made this problem of more importance than it was previously. Owing to these changes, it was not considered feasible in this report to consider with the care and thoroughness which the case demands the price-course of oil as of dates subsequent to March 1, 1913. From year to year new factors entered the problem, and the rate of increase for the future, when considered from the knowledge at hand as of dates subsequent to March 1, 1913, will probably be somewhat greater than those suggested in this report.

THE METAL BULLETIN of London calls attention to the critical state of the British smelting industry and, considering the possibility of obtaining zinc from other countries, points out that Germany, on account of lack of fuel and ore, is producing only about 3000 tons per month, no more than her own needs; that Belgium, producing now about 3000 tons per month, will need the

whole of her output in 1920 for sheet zinc; that France, on account of the destruction of her works and lack of coal, cannot be counted on for supplies in 1920; and that works in Holland are closed because of the prohibitive price of coal. The inference is that the United States will continue to export zinc to England at least for a year.

ANTIMONY before the War came chiefly from China, France, and Mexico. In France the production was largely from mines where the chief value of the ore was gold and the antimony was a by-product. The output of the principal mine has greatly decreased in recent years. The principal Mexican deposits occur in San Luis Potosi and Queretaro. Before the War the ore was chiefly exported to England; afterward a good deal of it came to the United States and a smelter was built at San Luis Potosi. The deposits in China have been developed during the past two decades, and formerly most of their product went to England for distribution. In 1915 the principal Chinese producers opened a sales office in the United States and now distribute direct to the American trade. Before the War the world's consumption of antimony was about 20,000 tons per year. During the War China produced at more than double this yearly rate. Accurate figures are lacking as to the output from Mexico, and France and its possessions, but it was certainly large. It is evident therefore that the world's present production capacity is far in excess of the normal demands. There was no production of antimony in the United States for some years previous to the War, other than in the form of antimonial lead, as already described. Deposits of antimony ores occur in a number of States, but the character and situation of the deposits is such as to make production costs too high to permit operation when the metal price is under 10c. per pound. In 1915, when the price was over 30c. per pound during most of the year, about 1500 tons of antimony was produced in the United States; but in 1917, when the price for most of the year was under 20c. per pound, the output fell off to 260 tons; and declined still further in 1918, when the price for the year averaged 12.58c. Certain individual deposits may be so fortunately situated as to permit operation at the normal price range (7c. to 10c. per pound) but in most cases the mining of antimony ores, except where their lead, silver, or gold content brings up the gross value to a working level, is not a profitable business in the United States at normal prices for the metal. From a military and economic standpoint it would seem desirable that industry in America should utilize the benefit of cheap antimony from abroad under normal trade conditions, and keep our own deposits intact as a reserve in case our overseas supply should be cut off in future wars.—Report for U. S. Bureau of Mines.

THE annual statement of the U. S. Geological Survey on the production of platinum and allied metals in 1918 is now available for distribution. A copy can be obtained by writing to the Survey at Washington, D. C.

Mr. Hoover's Address as President of the American Institute of Mining Engineers, on February 17, 1920

I have been greatly honored as your unanimous choice for President of this Institute with which I have been associated during my entire professional life. It is customary for your new president, on these occasions, to make some observations on matters of general interest from the engineer's standpoint.

The profession of engineering in the United States comprises not alone scientific advisors on industry but is in great majority comprised of the men in administrative positions. In such positions they stand midway between capital and labor. The character of your training and experience leads you to exact and quantitative thought. This basis of training in a great group of Americans furnished a wonderful recruiting ground for service in these last years of tribulation. Many thousands of engineers were called into the Army, the Navy, and civilian service for the Government. Thousands of high offices were discharged by them with credit to the profession and the nation.

We have in this country probably 100,000 professional engineers. The events of the past few years have greatly stirred their interest in national problems. This has taken practical form in the maintenance of joint committees for discussion of these problems and support to a free advisory bureau in Washington. The engineers want nothing for themselves from Congress. They want efficiency in government, and you contribute to the maintenance of this bureau out of sheer idealism. This organization for consideration of national problems has had many subjects before it, and I propose to touch on some of them this evening.

Even more than ever before is there necessity for your continued interest in this vast complex of problems that must be met by our Government. We are faced with a new orientation of our country to world problems. We face a Europe still at war; still amid social revolutions; some of its peoples still slacking on production; millions starving; and therefore the safety of its civilization is still hanging by a slender thread. Every wind that blows carries to our shores an infection of social disease from this great ferment; every convulsion there has an economic reaction upon our own people. If we needed further proof of the interdependence of the world, we have it today in the practical blockade of our export market. The world is asking for us to ratify long-delayed peace in the hope that such confidence will be restored as will enable her to reconstruct her economic life. We are today contemplating maintenance of an enlarged army and navy in preparedness for further upheavals in the world and failing to even provide some insurance against war by a league to promote peace.

Out of the strain of war, weaknesses have become even more evident in our administrative organization, in our

legislative machinery. Our Federal government is still over-centralized, for we have upon the hands of our Government enormous industrial activities which have yet to be demobilized. We are swamped with debt and burdened with taxation. Credit is woefully inflated; speculation and waste are rampant; our own productivity is decreasing. Our industrial population is crying for remedies to the increasing cost of living and aspiring to better conditions of life and labor. But, beyond all this, great hopes and aspirations are abroad; great moral and social forces have been stimulated by the War and will not be quieted by the ratification of peace. These are but some part of the problems with which we must deal. I have no fear that our people will not find solutions; but progress is sometimes like the old-fashioned rail fence—some rails are perhaps misshapen and all look to point the wrong way; but in the end, the fence progresses.

Your committees jointly with those of other engineering societies have had before them and expressed their views in many matters concerning the handling of the railways, shipping, the reorganization of Government engineering work, the national budget, and other practical items.

The war nationalization of railways and shipping are our two greatest problems in government control awaiting demobilization. There are many fundamental objections to continuation of these experiments in socialism necessitated by the War. They lie chiefly in their destruction of initiative in our people and the dangers of political domination that can grow from governmental operation. Beyond this, the engineers will hold that the successful conduct of great industries is to a transcendent degree dependent upon the personal abilities and character of their employees and staff. No scheme of political appointment has ever yet been devised that will replace competition in its selection of ability and character. Both shipping and railways have today the advantage of a skilled personnel, sifted out in the hard school of competition, and even then the government operation of these enterprises is not proving satisfactory. Therefore, the ultimate inefficiency that would arise from the deadening paralysis of bureaucracy has not yet had full opportunity for development. Already we can show that no government under pressure of ever-present political or sectional interests can properly conduct the risks of extension and improvement, or can be free from local pressure to conduct unwarranted services in industrial enterprise. On the other hand, our people have long since recognized that we cannot turn monopoly over to unrestrained operation for profit nor that the human rights of employees can ever be dominated by dividends.

Our business is handicapped on every side by the failure of our transportation facilities to grow with the coun-

try. It is useless to talk about increased production to meet an increased standard of living in an increasing population without a greatly increased transport equipment. Moreover, there are very great social problems underlying our transport system; today their contraction is forcing a congestion of our population around the great cities with all that these over-swollen settlements import. Even such great disturbances as the coal strike have a minor root in our inadequate transportation facilities and their effect upon the intermittent operation of our mines.

We are all hoping that Congress will find a solution to this problem that will be an advanced step toward the combined stimulation of the initiative of the owners, the efficiency of operation, the enlistment of the good-will of the employees, and the protection of the public. The problem is easy to state. Its solution is almost overwhelming in complexity. It must develop with experience, step by step, toward a real working partnership of its three elements.

The return of the railways to the owners places predominant private operation upon its final trial. If instant energy, courage, and large vision in the owners should prove lacking in meeting the immediate situation, we will be faced with a reaction that will drive the country to some other form of control. Energetic enlargement of equipment, better service, co-operation with employees, and the least possible advance in rates together with freedom from political interest will be the scales upon which the public will weigh these results.

Important phases of our shipping problem that have come before you should receive wider discussion by the country. As the result of war pressure, we will spend over \$2,800,000,000 in the completion of a fleet of 1900 ships of a total of 11,000,000 tons—nearly one-quarter of the world's cargo shipping. We are proud of this great expansion of our marine, and we wish to retain it under the American flag. Our shipping problem has one large point of departure from the railway problem, for there is no element of natural monopoly. Anyone with a watertight vehicle can enter upon the seas today, and our Government is now engaged upon the conduct of a nationalized industry in competition with our own people and all the world besides. While in the railways government inefficiency could be passed on to the consumer, on the seas we will sooner or later find it translated to the national Treasury.

Until the present time, there has been a shortage in the world's shipping, but this is being rapidly overtaken and we shall soon be met with fierce competition of private industry. If the Government continues in the shipping business, we shall be disappointed from the point of view of profits. For we shall be faced with the ability of private enterprise to make profits from the margins of higher cost of government operation alone. Aside from those losses inherent in bureaucracy and political pressure, there are others special to this case. The largest successfully managed cargo fleet in the world comprises about 120 ships and yet we are attempting to manage

1900 ships at the hands of a government bureau. In normal times the question of profit or loss in a ship is measured by a few hundred tons of coal wasted, by a little extravagance in repairs, or by the four or five days added on a round trip. Beyond this, private shipping has a free hand to set up such give-and-take relationships with merchants all over the world as will provide sufficient cargo for all legs of a voyage, and these arrangements of co-operation cannot be created by government employees without charge or danger of favoritism. Lest fault be found, our government officials are unable to enter upon the detailed higgling in fixing rates required by every cargo and character. Therefore, they must take refuge in rigid regulations and in fixed rates. In result, their competitors underbid by the smallest margins necessary to get the cargoes. The effect of our large fleet in the world's markets is thus to hold up rates, for so long as this great fleet in one hand holds a fixed rate, others will only barely under-bid. If we hold up rates, an increasing number of our ships will be idle as the private fleet grows. On the other hand, if we reduce rates we shall be under-bid until the government margin of larger operation cost causes us to lose money.

We shall yet be faced with the question of demobilizing a considerable part of this fleet into private hands, or frankly acknowledging that we operate it for other reasons than interest on our investment. In this whole problem there are the most difficult considerations requiring the best business thought in the country. In the first instance, our national progress requires that we retain a large fleet under our flag to protect our national commercial expansion overseas. Secondly, we may find it desirable to hold a considerable government fleet to build up trade-routes in expansion of our trade, even at some loss in operation. Thirdly, in order to create this fleet, we have built up an enormous ship-building industry. Fifty per cent of the capacity of our ship-yards will more than provide any necessary construction for American account. Therefore there is a need of obtaining foreign orders, or the reduction of capacity, or both. I believe, with most engineers, that, with our skill in repetitive manufacture, we can compete with any ship-builders in the world and maintain our American wage-standards; but this repetitive manufacture implies a constant flow of orders. It would seem highly desirable, in order to maintain the most efficient yards until they can establish themselves firmly in the world's industrial fabric, that the Government should continue to let some ship construction contracts to the lowest bidders; these contracts to supplement private building in such a way as to maintain the continuous operation of the most economical yards and the steady employment of our large number of skilled workers engaged therein.

When we consider giving orders for new ships, we must at the same time consider the sale of ships, as we cannot go on increasing this fleet. When we consider sale, we are confronted with the fact that our present ships were built under expensive conditions of war, costing from three to four times per ton the pre-war amount, and that

already any merchant, subject to the long time of delivery, can build a ship for 75% of their cost. It would at least seem good national policy to sell ships today for the price we can contract for delivery a year or two hence, thus making the Government a reservoir for continuous construction. We could thus stabilize building industry to some degree and also bring the American-owned fleet into better balance, if, as the Government sold three or four emergency constructed cargo vessels, it gave an order for one ship of a better and faster type. This would make reduction in our ship-building steadier and would give the country the type of ships we need.

Our joint engineering committees have examined with a great deal of care into organization of and our expenditure on public works and technical services. These committees have consistently and strongly censured the appalling inefficiency in the Government organization of these matters. They report to you that the annual expenditure on such works and services now amounts to over \$250,000,000 per annum, and that they are carried out today in nine different governmental departments. They report that there is a great waste by lack of national policy of co-ordination, in overlapping with different departments, in competition with each other in the purchase of supplies and materials and the support of many engineering staffs.

They recommend the solution that almost every other civilized government has long since adopted, that is, the co-ordination of these measures into one department under which all such undertakings should be conducted and controlled. As a measure practical to our Government, they have advocated that all such bureaus should be transferred to the Interior Department, and all the bureaus not relating to these matters should be transferred from the Interior to other departments. The committee concludes that no properly organized and directed saving in public works can be made until such a re-grouping and consolidation is carried out, and that all of the cheese-paring that normally goes on in the honest effort of Congressional committees to control departmental expenditure is but a tithe of that which could be effected if there were some concentration of administration along the lines long since demonstrated as necessary to the success of private business.

Another matter of government organization to which our engineers have given adhesion is in the matter of the national budget. To minds charged with the primary necessity of advance planning, co-ordination, provision of synchronizing parts in organization, the whole notion of our hit-or-miss system is repugnant. A budget system is not the remedy for all administrative ills; it provides a basis of organization that at least does not paralyze administrative efficiency as our system does today. Through it, the co-ordination of expenditure in government departments, the prevention of waste and overlapping in government bureaus, the exposure of the pork barrel, and the balancing of the relative importance of different national activities in the allocation of our national income can all be greatly promoted. Legislation would also be

expedited. No budget that does not cover all government expenditure is worth enactment. Furthermore, without such reorganization as the grouping of construction departments, the proper formulation of a budget would be hopeless. The budget system in some form is so universal in civilized governments and in competently conducted business enterprise, and has been adopted in thirty of our States, that its absence in our Federal government is most extraordinary. It is, however, but a further testimony that it is always a far cry of our citizens from the efficiency in their business to interest in the efficiency of their government.

Another great national problem to which every engineer in the United States is giving earnest thought, and with which he comes in daily contact, is that of the relationship of employer and employee in industry. In this, as in many other national problems today, we are faced with a realization that the science of economics has altered from a science of wealth to a science of human relationships to wealth. We have gone on for many years throwing the greatest of our ingenuity and ability into the improvement of processes and tools of production. We have until recently greatly neglected the human factor that is so large an element in our very productivity. The development of vast repetition in the process of industry has deadened the sense of craftsmanship and the great extension of industry has divorced the employer and his employee from that contact that carried responsibility for the human problem. This neglect of the human factor has accumulated much of the discontent and unrest throughout our great industrial population and has reacted in a decrease of production. Yet our very standards of living are dependent on a maximum productivity up to the total necessities of our production.

Another economic result is, or will be yet, a repercussion upon the fundamental industry of the United States, that is, agriculture. For the farmer will be unable to maintain his production in the face of a constant increase in the cost of his supplies and labor through shrinkage in productivity in other industries. The penalty of this disparity of effort comes mainly out of the farmer's own earnings.

I am daily impressed with the fact that there is but one way out, and that is to again re-establish through organized representation that personal co-operation between employer and employee in production that was a binding force when our industries were smaller of unit and of less specialization. Through this, the sense of craftsmanship and the interest in production can be re-created and the proper establishment of conditions of labor and its participation in a more skilled administration can be worked out. The attitude of refusal to participate in collective bargaining with representatives of the employees' own choosing is the negation of this bridge to better relationship. On the other hand, a complete sense of obligation to bargains entered upon is fundamental to the process itself. The interests of employee and employer are not necessarily antagonistic; they have a great common ground of mutuality and if we could secure emphasis

upon these common interests we would greatly mitigate conflict. Our Government can stimulate these forces, but the new relationship of employer and employee must be a matter of deliberate organization within industry itself. I am convinced that the vast majority of American labor fundamentally wishes to co-operate in production and that this basis of good-will can be organized and the vitality of production re-created.

Many of the questions of this industrial relationship involve large engineering problems, as an instance of which I know of no better example than the issue you plan for discussion tomorrow in connection with the soft coal industry. Broadly, here is an industry functioning badly from an engineering and consequently from an economic and human standpoint. Owing to the intermittency of production, seasonal and local, this industry has been equipped to a peak load of 25 or 30% over the average load. It has been provided with a 25 or 30% larger labor complement than it would require if continuous operation could be brought about. I hope your discussion will throw some light on the possibilities of remedy. There lies in this intermittency not only a long train of human misery through intermittent employment, but the economic loss to the community of over 100,000 workers who could be applied to other production, and the cost of coal could be decreased to the consumer. This intermittency lies at the root of the last strike in the attempt of the employees to secure an equal division among themselves of this partial employment at a wage that could meet their view of a living return on full employment.

These are but few of the problems that confront us. But in the formulating of measures of solution, we need a constant adherence to national ideals and our own social philosophy.

In the discussion of these ideals and this social philosophy, we hear much of radicalism and of reaction. They are, in fact, not an academic state of mind but realize into real groups and real forces influencing the solution of economic problems in this community. In their present day practical aspects, they represent on one hand roughly various degrees of exponents of socialism, who would directly or indirectly undermine the principle of private property and personal initiative, and, on the other hand, those exponents who in various degrees desire to dominate the community for profit and privilege. They both represent attempts to introduce or preserve class privilege, either a moneyed or a bureaucratic aristocracy. We have, however, in American democracy an ideal and a social philosophy that sympathizes neither with radicalism nor reaction as they are manifested today.

For generations the American people have been steadily developing a social philosophy as part of their own democracy—and in these ideals, it differs from all other democracies. This philosophy has stood this period of test in the fire of common sense; it is, in substance, that there should be an equality of opportunity—an equal chance—to every citizen. This view that every individual should, within his lifetime, not be handicapped in

securing that particular niche in the community to which his abilities and character entitle him, is itself the negation of class. Human beings are not equal in these qualities. But a society that is based upon a constant flux of individuals in the community, upon the basis of ability and character, is a moving virile mass; it is not a stratification of classes. Its inspiration is individual initiative. Its stimulus is competition. Its safeguard is education. Its greatest mentor is free speech and voluntary organization for public good. Its expression in legislation is the common sense and common will of the majority. It is the essence of this democracy that progress of the mass must arise from progress of the individual. It does not permit the presence in the community of those who would not give full need of service.

Its conception of the State is one that, representative of all the citizens, will in the region of economic activities apply itself mainly to the stimulation of knowledge, the undertaking only of works beyond the initiative of the individual or group, the prevention of economic domination of the few over the many, and the least entrance into commerce that government functions necessitate.

The method and measures by which we solve this accumulation of great problems will depend upon which of these three conceptions will reach the ascendancy among our people.

If we cling to our national ideals it will mean the final isolation and the political abandonment of the minor groups who hope for domination of the Government, either by 'interests' or by radical social theories through the control of our political machinery. I sometimes feel that lawful radicalism in politics is less dangerous than reaction, for radicalism is blatant and displays itself in the open. Unlawful radicalism can be handled by the police. Reaction too often fools the people through subtle channels of obstruction and progressive platitudes. There is little danger of radicalism ever controlling a country with so large a farmer population, except in one contingency. That contingency is from a reflex of continued attempt to control this country by the 'interests' and other forms of our domestic reactionaries.

The mighty upheaval following the world war has created turmoil and confusion in our own country no less than in all other lands. If America is to contribute to the advance of civilization, it must first solve its own problems, must first secure and maintain its own strength. The kind of problems that present themselves are more predominantly economic—national as well as international—than at any period in our history. They require quantitative and prospective thinking and a sense of organization. These are the sort of problems that your profession deals with as its daily toil. You have an obligation to continue the fine service you have initiated and to give it your united skill.

MAGNESITE, the natural carbonate of magnesium, when calcined, forms a highly refractory material which has no thoroughly satisfactory substitute in the open-hearth process for making steel.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ALASKA

NOTES FROM HYDER.

HYDER.—That there will be something approaching a rush into the Salmon River district, in northern British Columbia, as soon as the season breaks appears certain. The development at the Premier mine and work on other properties in the vicinity, together with the staking of many new claims, have had the effect of attracting widespread attention to this part of the northern country. The towns of Hyder and Stewart, the portals through which prospectors and miners must pass, are booming. Real estate is said to be selling at high figures in both towns and it is known that many enterprising businessmen are waiting only for more propitious weather to establish themselves. Dale Pitt, assistant manager of the Premier mine, says that there is a misleading impression that the country is another Klondyke. He adds that it should be understood that it is a hard-rock camp and that money is needed to develop it. For the benefit of those who may not understand the conditions, Pitt's statement may be supplemented. In and around Hyder the snow usually remains until the month of April and in the hills it often persists until June. Although everything possible is being done to prepare for the accommodation of the hundreds of visitors looked for, those proposing the trip will be well advised to carry with them tents and blankets. The short road between Stewart and Hyder that involved extremely heavy and expensive construction is complete. The Premier company, it is understood, carried the road from Hyder through American territory to the Canadian boundary, from which point it was taken up by the Provincial authorities. It is announced that a special mail contract has been entered into for the benefit of the people of Stewart whereby mails are to be conveyed once a week during the winter and twice a week during the summer, transportation to be provided by a substantial powerboat.

ARIZONA

OPERATIONS AT KINGMAN AND OATMAN.

AJO.—The first diamond-drill hole on the Cornelia Extension has been completed and the second one has been commenced. The first hole was drilled to a depth of 800 ft. and is said to have revealed conditions satisfactory to the management.

KINGMAN.—Preparations are being made to install an electric hoist at the Emerald Isle property. The shaft in the west orebody is now down 50 ft. and has been sunk

through desert wash and gravel which has been cemented by oxidized copper minerals. Plans have been completed for an enlargement of the present electrolytic plant. Considerable excitement has been caused in Oatman by the opening of a large orebody in a cross-cut from the tunnel level of the Alexander mine of the Oatman Southern Mining Co. Owing to lack of money this property has been idle during the past year. The shaft of the Kingman has reached a depth of 30 ft. and a hoist and compressor have been installed. The property formerly went under the name of the Tipperary Mining Company.

Messrs. Ihms and Hunt have opened a streak of high-grade silver ore in the Wallapai district, that is said to assay as high as 2000 oz. in silver per ton. The discovery was made close to the Hibernia property. There is considerable prospecting being done for silver in the vicinity of the Hibernia. The returns from shipments made by the McCracken Silver Lead Mines Co. during January showed a net return of \$2995. Four new tables have been installed in the mill and it is expected that this change will double the capacity of the mill.

MIAMI.—The vein of the Superior & Boston has been entered at a point 400 ft. east of the place where it was found on the 400-ft. level and shows an average of seven feet of excellent copper ore. Shipments of ore continue at the rate of five cars per week. Sinking of the shaft of the Iron Cap is being continued to the 1500-ft. level. Rapid progress is being made on the concentrator and the grading for the narrow-gauge railroad from the mine to the mill is nearing completion. Production is at the rate of 250 to 300 tons per day.

PATAGONIA.—It has been announced by H. K. Welch, president of the Hardshell Mining Co., that the new shaft which is now being sunk has reached the 400-ft. level. Sinking is to be continued to 500 ft., at which point cross-cutting will be done. Water has delayed sinking and has necessitated the installation of increased pumping facilities.

RAY.—The Gila Copper Sulphide Co. has been turned back to its owners by formal action of the United States court of Arizona, the receivership having been dismissed. The company has been reorganized and has ample capital.

TUCSON.—It is understood that a New York announcement has been made to the effect that the Mineral Hill Consolidated Copper Co., operating in the San Xavier district, twelve miles south of Tucson, is to undertake extensive development. It is also stated that negotiations are under way for an eight-mile railway to connect

the mine with the main line of the Southern Pacific railroad. Plans are completed for the erection of a 300-ton mill, there now being 500,000 tons of ore developed averaging more than 2% copper. The El Tiro Leasing Co. produced 262,600 lb. of copper in December, one-third of which came from development work. Drifting toward the Williams shaft on the 200-ft. level is being continued and raising on drill-hole No. 58 from the 200-ft. level is being done to open the high-grade ore which the drill passed through. Ore which was opened up on the 50 and 100-ft. levels has been proved on the 200-ft. level. Copper production is being curtailed awaiting a more favorable market.

COLORADO

VINDICATOR OFFICERS ELECTED.—LESSEES AT LEADVILLE ARE PRODUCING GOOD ORE.

CROFTLE CREEK.—The annual meeting of the Vindicator Consolidated Gold Mining Co., recently held in Denver, resulted in the re-election of the old board of directors and officers. Guilford S. Wood is president; Adolph F. Zang, vice-president; George A. Stahl, secretary and general manager; Philip A. Zang, treasurer; and A. E. Carlton, Charles Sigel, Jr., and D. W. Strickland complete the board of directors. The annual report shows that despite the fact that the cost of mining supplies and labor continued at the highest level ever known, and the shortage of labor became more acute from month to month, operating profits totaled \$98,958 from gross production of \$692,041. This total includes the earnings from the ferro-alloy plant at Denver. During 1919 the company hoisted 143,400 tons of ore on company account, from which was produced 19,922 tons of shipping-ore with a gross value of \$718,136. The cost of marketing was \$129,250 and net returns \$588,885. Lessees produced 55,648 tons and shipments from this source aggregated 20,772 tons with a gross value of \$291,064. Royalties paid on lessees' shipments amounted to \$92,525.

The Lincoln Mines & Reduction Co. has started underground development of the Ironclad Hill properties of the Rex M. & M. Co., held under bond and lease. The Lincoln company's mill is on this ground and will shortly be operating. Recent tests have proved the newly-developed Gasche process to be suitable for the treatment of ores from the Ironclad Hill mine.

LEADVILLE.—Shipments aggregating ten cars monthly of lead-carbonate ore are leaving the Matchless mine, operated under bond and lease by Albert R. Bailey of Pueblo and associates, and heavy shipments from the orebody recently opened up in the No. 6 shaft will soon follow. Parts of the orebody are rich in silver and lead but the ores are not sorted prior to shipment. Prospecting work below the original discovery in the No. 6 shaft has indicated that the shoot is continuous. At the Lilian mine in Iowa gulch, Tim Riley, Samuel Thomas, and the Mereray brothers, who secured control about six months ago, are extending the tunnel to cut the shoots found in the upper workings. The tunnel will cut this unex-

ploited territory at a depth of 300 ft. The tunnel through which the operators are working was driven 40 years ago, and was badly caved when work commenced. It makes a convenient portal to the lower formation of the Iowa Gulch section. James Boni and Frank Barry, operating the Ollie Reed No. 2 property, are shipping a good grade of lead-silver carbonate ore, while drifting to get under a new orebody recently cut in the level above. With the shoot proved continuous a large body of ore will be available for stoping.

OURAY.—A rich vein of silver ore has been found in the Early Bird group of mines, on the divide between Animas Forks and Ouray. The owners, A. E. McCormick, George Gardner, Clay Ashley, and James Bass, purchased the property from a Pueblo company late last fall and they began to break trail to their mine on December 6. When work was begun the tunnel already was advanced 150 ft., and after driving 20 ft. farther a vein of copper and silver ore one foot wide was found. One sample assayed 14,000 oz. silver and 10% copper. Eighteen mules are packing the ore to Ouray, which is the shipping point. A car of ore will be completed this week.

MICHIGAN

OUTPUT OF COPPER DURING JANUARY.

HOUGHTON.—The completed compilation of the production of copper ore from the mines of the Lake Superior district, together with the actual or estimated reports of the smelter output of refined copper, indicate an increase over the figures for December 1919. With the exception of two, all the mines show an increase for January. In the case of Calumet & Hecla this increase was over 800,000 lb. The table follows:

Mine	Tonnage	Pounds per ton		Refined	Refined
		January	December	January	December
Ahmec	64,125	23.9	25.0	1,533,300	1,495,081
Allouez	20,000	20.0	19.2	400,000	376,100
Baltic	15,000	35.0	35.0	525,000	490,000
Calumet & Hecla	218,488	25.0	25.0	5,462,220	4,669,336
Centennial	7,500	16.6	18.6	122,600	124,311
Champion	49,000	40.0	40.0	1,960,000	1,840,000
Isle Royale	58,889	18.0	17.8	1,060,094	970,000
Michigan	4,148	25.3	21.0	104,848	98,467
Mohawk	46,629	21.88	20.09	1,020,212	1,019,904
Oscoda Con.	55,000	14.31	16.0	787,300	895,000
Quincy	99,000	18.0	18.0	1,782,000	1,728,000
Trimountain	14,500	30.0	30.0	435,000	435,000
Victoria	7,850	18.0	12.0	125,000	167,000
Wolverine	20,022	13.62	14.63	281,052	327,970
Winona	11,000	13.9	16.0	153,140	147,420
White Pine	16,257	20.0	20.0	325,157	346,939

NEVADA

LESSEES ARE ACTIVE AT GOLDFIELD.—CANDELARIA PROPERTY BEING SAMPLED.

ARROWHEAD.—Enlarging of the shaft of the Arrowhead has been nearly completed and lateral work will be resumed soon. The shaft was too small for the amount of work being done and also was considered unsafe. Nineteen companies are working in the district, practically all sinking shafts, and some are using machine drills. The Arrowhead Consolidated company is cutting a station at 150 feet.

ROUND MOUNTAIN.—The Silver Shield, in Horse canyon, which was optioned recently by Tonopah and Gold-

field men, is being examined by engineers representing Eastern capital with a view to purchase. Five working faces, two in the main tunnel and three in tunnels lower in the vein, are in ore of shipping grade. A winze from the main tunnel has been sunk 60 ft. in rich ore that has shown a gradual increase in value. A 3-ft. shoot assays from 300 to 500 oz., according to one of the holders of the option. The lower tunnel, started recently, will cut the vein at a depth of 750 feet.

TONOPAH.—Labor conditions are again normal at Tonopah and Divide following the recent trouble. From 800 to 900 men are employed in both districts. Many are idle because of the refusal of the mine owners to employ them. It is said by members of both parties to the recent

Houlahan and his son, John Houlahan, refuse information on conditions. The Houlahans control the company, which has done a large amount of development work. The shaft is over 400 ft. deep and thousands of feet of lateral work has been done in a vein over 25 ft. wide. The ore being shipped assays from \$50 to \$100 per ton, according to reports, but the rate of shipment is slow. According to reliable reports the Eagle contains a body of mill-grade ore of sufficient size to make it of great value, in view of the rise in the price of silver. The ore contains much sulphur and arsenic. Officials of the Yellow Tiger report that the assessment has been paid on 85% of the outstanding stock. The surface of the ground owned by the company is being prospected, but the man-

VIRGINIA CITY, THE SCENE OF REVIVED ACTIVITY

dispute that there is no danger of further trouble for the present.

CACTUS.—Bids are being received by the Cactus Nevada for sinking the shaft 100 ft. from the present depth of 200 ft. and, as \$10,000 is now available, it is thought work will start within a month; the present fund being increased as stock is sold in the East. The shaft will be sunk to 600 ft., contracts being let for each 100 ft. The west drift on the 160-ft. level has cut an ore-shoot opened on the 100-ft. level and assays of 75 to 100 oz. silver are being secured.

TULE CANYON.—Work is to be started on the Ingalls on March 12 by the holders of the option. The option was for 30 days from February 12, and Harry Stimler, who negotiated the sale, secured an extension for one month by paying \$1000. The former owners are treating in the mill a small tonnage of ore mined before the sale was made.

GOLDFIELD.—The Nevada Eagle, $3\frac{1}{2}$ miles west of here, has resumed shipments of silver ore after years of idleness during which the mine was almost forgotten. J. M.

agement reports that no deep work will be undertaken while the present unfavorable conditions for the development of gold prospects exist. The company is in a strong financial position. The Dunn lease on the Engineers' block in the Florence has shipped a carload of \$32 ore and the Adamson, Traynor, and McCall lease has shipped a carload of \$40 ore. Interest-centres on the Cracker Jack lease, which promises to develop into a larger producer than the Florence Divide was last year, according to R. C. McCarthy, superintendent of the Florence. Ore containing free gold in quantity has been opened on the 500-ft., or bottom, level of the Little Florence shaft in the Cracker Jack lease, and a shoot of high-grade ore also is being developed on the 258-ft. level of the Florence shaft. Good ore has been found at a number of other places heretofore unexplored, but it will require from two weeks to a month to determine whether the ore is persistent for a distance sufficient to make the shoots of value. At a depth of 1022 ft. the Spearhead company is drifting in a quartz-filled fissure in the granite. The drift is being driven from the bottom of a winze from the 910-ft. level.

CANDELARIA.—Edwin S. Giles, Goldfield mining engineer, recently inspected the Georgene, adjoining the Candelaria, and it is reported that the Jackling interests, said to control the Candelaria, are planning to take over an option held by Goldfield men. The Georgene has been developed to a depth of 450 ft. In the early days ore assaying less than \$25 could not be handled at a profit and the filling in large stopes assays from 10 to 12 oz. silver. There is a large undeveloped area in which a number of the main veins of the district centre and this is thought to be the reason the Jackling interests are anxious to secure the Georgene. The silver is found in altered limestone and crushed porphyry and the ore occurs in lenses in the veins. According to Mr. Giles, the timbers are as good as when put in place and in general the mine is in nearly perfect condition. The engineer found in the mine a copy of the 'Mining and Scientific Press' issued in 1889 in newspaper form and containing an article on the Candelaria district in which the Georgene was mentioned. Charles D. Kaeding, manager for the Dome Mines Co. at Poreupine, is in charge of the sampling of the Candelaria and 10,000 samples will be taken.

TECOPA.—Shipments of tale are being made from Acme, north of here, to Los Angeles, where the material is ground and shipped to the Colgate company for use as talcum powder. The tale, which occurs in veins from 2 to 20 ft. wide, is mined through an 80-ft. shaft. The rate of shipment is slow and the profits are small because of the long railroad hauls and because frequent increase in the lime content makes considerable prospecting necessary.

UTAH

SYMPATHETIC STRIKE AT PARK CITY IS A FAILURE.—MINERS STILL OUT AT BINGHAM.

BINGHAM.—The United States company's mines at Bingham produced 130,911 dry tons of ore during 1919, from which was obtained 21,814 oz. gold, 575,868 oz. silver, 20,061,757 lb. of lead, 1,045,060 lb. of copper, and 130,911 lb. of zinc, having a gross value of \$2,438,385. The cost of extraction was \$720,495; of reduction, \$1,467,025; of transportation, \$85,802; and of construction, \$8765; a total of \$2,282,078; leaving net proceeds for the year, \$156,307.

The strike which became effective on the morning of February 10 is still on, according to I. W. W. leaders. At most of the mines, except the United States, a number of employees have returned to work, but it is estimated that fully 600 miners have left town, and even if the strike should be called off, it would be some time before the mines could build their forces up to what they were on February 9. Operations of the Utah Copper company have continued without any interruption.

EUREKA.—Nineteen mines in this district shipped a total of 141 cars of ore during the week ending February 14, as compared with 175 earloads for the previous week. The Chief Consolidated shipped 42 earloads; the Dragon, 20; Tintie Standard, 18; Eagle & Blue Bell, 11; Iron

Blossom, 10; Gemini, 8; Colorado, 7; Grand Central, 7; Centennial-Eureka, 5; Bullion Beck, 3; Swansea, 3; Victoria, 3; Sunbeam, 2; Ridge & Valley, 2; Mammoth, 2; Eureka Mines, 1; Godiva, 1; K. C., 1; Alaska, 1.

The Centennial-Eureka mine, owned by the United States Smelting, Refining & Mining Co., produced 21,288 tons of ore during 1919, having a gross value of \$514,017. This tonnage yielded 7458 oz. gold, 230,007 oz. silver, 54,712 lb. of lead, and 601,567 lb. of copper. Total costs were \$494,794, of which \$252,474 was expended on extraction; \$192,592 on reduction; and \$49,727 on transportation; leaving net proceeds of only \$19,223.

Stockholders of the Selma Mines Co. at a recent meeting elected the following directors: W. I. Snyder, J. C. Jensen, R. A. Brown, C. J. Peterson, and E. T. Walton. At a directors' meeting which followed, W. I. Snyder was elected president; J. C. Jensen, vice-president; and Gideon Snyder, secretary-treasurer. The property of this company, consisting of 560 acres, adjoins the Tintie Paymaster mines on the south, with the Chief Consolidated and the Central Standard also adjacent. A shaft, one compartment, and a manway, has been sunk upon a large fissure to the 250-ft. level. At this depth about 2500 ft. of drifting has been done. A mineralized zone was penetrated, but inasmuch as the formation indicated that leaching action had taken place, it was decided that sinking would be continued.

Three feet of rich ore, with gray copper and chalcopyrite predominating, is showing in the face of the south drift of the Eureka Lilly mine on the 1650-ft. level. It is the opinion of the officials of the company that a cross-break is being approached, and interesting developments are looked for.

A full face of first-class ore was found on the 1450-ft. level of the Tintie Standard mine shaft No. 2, according to E. J. Raddatz, president. The 1450-ft. level is the lowest in the mine. Recently a station was cut on this level and an east drift started from the shaft. The find was made at a distance of approximately 120 ft. from the shaft, and inasmuch as it was made on the lowest level, it is of extra importance.

Drifting from the 350-ft. level of the Tintie Paymaster mine is continuing steadily, and nine feet is being made each day. In the last 600 ft. of drifting, three veins from 5 to 14 ft. wide have been cut. In another 200 ft. it is expected that an important north-south fissure, which on the surface shows promising mineralization, will be cut at a vertical depth of approximately 500 feet.

PARK CITY.—An average of 20 tons per day is being produced by the Naildriver mine; this output will be materially increased as soon as better hauling and storing facilities can be arranged. The last shipment to a valley smelter averaged 31 oz. silver and 11% lead. In the Dunyon cross-cut in the foot-wall of the vein on the 600-ft. level, four feet of ore, averaging 30 oz. silver and 10% lead, has been followed for a distance of 30 feet.

An effort on the part of Albert Wills, I. W. W. agent, and other bearers of the red card, to start a strike of miners in this district in sympathy with the striking

Bingham miners, failed on February 15. A meeting had been called by Wills, which was attended by 250 miners. A. J. Berg, secretary of the local of the International Mine, Mill & Smelter Workers' Union, a branch of the American Federation of Labor, got the floor and vigorously denounced Wills and the I. W. W.'s in general, saying that he had been converted against them after statements made by Wills at the time of the strike in this camp last summer. Berg accused Wills of preaching a doctrine of destruction. A vote was then taken on the proposition of striking, only 15 men voted in favor. The identity of these 15 men is not known, but it is said that most of them came into camp during the two or three days preceding the meeting, apparently from the Bingham district. A day or two after the meeting, demands were sent by mail to all of the local mines, asking for a \$6

BRITISH COLUMBIA

LEGISLATION REGARDING PLACER CLAIMS EXPECTED.

VICTORIA.—Mining men anticipate that some important amendments to the Placer Mining Act of British Columbia will be considered by the Provincial Legislature during the session now in progress. There are over 1100 placer-mining leases in the Province, of which something over 170 are fully paid up in regard to their rentals. The arrears can be readily understood when it is stated that the annual fee for a creek claim is \$75 and that for a bench claim \$50 and that \$1000 assessment work is required on each lease, making a very considerable sum in the aggregate. It is thought likely that the fees will be reduced, especially in respect of the amount of assessment work required, which will be placed more on a par with

FIRST STREET, STEWART, BRITISH COLUMBIA

minimum wage; an 8-hour day, collar to collar; and similar concessions demanded at Bingham. No attention was paid to these letters, and on February 17 a strike was supposed to become effective. About 20 men, newcomers in the camp, drew their time. On the evening of the 17th, a crowd of 150 miners gathered with the avowed intention of running all I. W. W.'s out of the district, but cool heads advised against violence, and the agitators, who were under cover, were not molested. The action of the agitators in this district is the same as in other mining camps. Not expecting their demands to be granted, they followed them up with a strike order, without giving mine owners sufficient time even to discuss the matter among themselves.

ALTA.—The Columbus Rexall Mining Co. produced 1337 tons of ore during 1919, from which was obtained 7842 oz. silver and 148,950 lb. of copper, the gross value of which was \$39,688.

The Little Cottonwood Transportation Co. may resume operations March 1, if present favorable weather conditions continue, according to Shand Smith, manager.

the terms of the Mineral Act; only \$100 assessment work per annum is asked for on a lode claim. Probably some arrangement will be made for the payment of arrears on leases which have been under development or upon which it can be satisfactorily shown that development is planned. But such ground as is held, manifestly, for purposes of speculation no doubt will be thrown open and the leases cancelled.

With the requirement by the Consolidated Mining & Smelting Co. of a bond on the Big Interior group of claims, situated about ten miles from the head of Great Central lake, on Vancouver Island, energetic development of the property is expected. It has been handicapped by lack of transportation, and since the expense of proving its value is necessarily large, little has been done heretofore in the way of development.

ALICE ARM.—Despite the fact that the district is in the grip of a more than usually severe winter, there is activity at the mines. The Dolly Varden mine has been sending about 2½ tons of ore per day to tide-water in sleds drawn by dogs and horses. The use of this form of

transit, over the 18 miles between the mine and tide-water, in preference to waiting until spring, indicates the unusually high grade of the ore. The ore is being shipped to the Selby smelter. The Taylor Engineering Co. is establishing a camp at the Wolf mine, where a building for a compressor is being erected. As soon as the weather permits, the Alice Arm-Dolly Varden railway is to be extended to this mine. This extension will benefit the North Star, Torie, Tiger, Musketeer, and other mines. A quantity of ore is ready for shipment at the North Star mine, but will be held pending the extension of the railway. Price & Keith, of New York, who are interested in the Premier mine, have bonded the Last Chance mine and have a diamond-drill working two shifts per day. As soon as the exploration work has been completed, the drill will be moved to a property owned by E. Pickell, which has been bonded to the same syndicate. A steam-driven compressor will be installed at the Dolly Varden, to replace the two gasoline-driven compressors, which have not given satisfaction.

SLOCAN.—M. S. Davys will operate the Hewill mine, at Silvertown. This mine was bonded by Clarence Cunningham, but the bond was relinquished after a season's exploration work. The Standard mine is coming rapidly to the front again. During December a profit of \$30,016 was made, against \$7598 for the previous month. The Silversmith Mines, Ltd., has decided to call in its preferred stock and to issue common in its stead. The issue of common up to the end of last year totaled \$103,044 and the preferred \$165,193, of which latter \$99,239 was subject to call. During last year 14,558 tons of ore was mined; 325 tons of high-grade ore was sent direct to the smelter; and the balance was concentrated in the company's mill. The resulting concentrate was divided between Trail and United States smelters, Trail receiving 19 cars of lead and 3 cars of zinc concentrate and the United States smelters getting 17 cars of lead and 21 cars of zinc concentrate. There is an estimated ore-reserve in the mine of 90,000 tons. A. L. McPhee and Pat Maguire, who leased the Ottawa mine from the Consolidated company, have sent over 100 tons of ore to Trail during the winter. Maguire and J. T. Tipping are developing the Republic mine and have a car of ore ready to ship. M. S. Davys has purchased a controlling interest in the Silver Bear mine. This property was bonded by R. F. Green and partner with the view to operating it with the Silver Bell, but the bond was relinquished.

ONTARIO

PRODUCTION AT NIPISSING.

During the week ending February 13 the Nipissing company and the Mining Corporation shipped 401,000 oz. of silver bullion. The indicated price of \$1.55 per ounce makes a total value of \$622,000 for the week's shipments, all of which were consigned to the Far East, payment being made in New York. For the month of January the Nipissing mine produced \$329,401. Hugh Park, manager, in his monthly report, states: "Underground development and production were satisfactory for the

month, notwithstanding that it was a short period, as a result of the annual clean-up at the mills and general repair work at the various shafts." Max Morgenstern, of New York, a minority shareholder in the Buffalo Mines, has applied for an injunction restraining the Mining Corporation from exercising what was believed to be its rights in connection with the Buffalo mine, following the recent purchase of control.

W. E. Simpson has been appointed engineer and general manager of the Miller Independence mines, on Boston creek. The property came into prominence about a year ago following the discovery of a vein containing calaverite in spectacular quantities. Nine years experience mining telluride ore in Western Australia especially fits Mr. Simpson for his present position. The Miners' Union in this district is arranging to take a referendum of its member for the purpose of determining its future course; that is, whether it will remain with the International or break away and form a district organization.

TORONTO.—An organization to be known as the Ontario Mining Association has been formed with a view to promoting the interests of the mining industry. Details of organization have not been completed, but officers were elected as follows: President, A. D. Miles, of the International Nickel Co.; first vice-president, F. L. Culver, president of Beaver and Kirkland Lake mines; second vice-president, G. C. Bateman, general manager La Rose mine; secretary, B. Neilly. A company without capital will be incorporated and an office maintained at Toronto.

PORCUPINE.—The McIntyre has opened up three levels below 1000 ft., at 1125, 1250, and 1375 ft., and is establishing a main tramming level at 1375 ft. An excellent grade of ore is being opened up and preparations are being made for stoping. The shaft has now reached a depth of 1500 ft. The company is encountering serious difficulties from water in its operations on the Plenaurum property, which may result in its option being dropped.

At the Dame Lake drifting is being done on the 600-ft. level to pick up orebodies indicated by diamond-drilling, which have yielded high assays. The mill during the three months in which it was in operation last year treated 4433 tons of ore with a recovery of \$23,832. The North Davidson is getting machinery for a mining plant, which will be installed as soon as possible.

KIRKLAND LAKE.—The camp is experiencing a decided boom, a large number of properties having lately changed hands. The Lebel township section of the area is attracting many investors. The Kirkland Combine and Boston McCrear companies have taken over claims in this neighborhood and several important transactions are being negotiated. The Wood-Kirkland has engaged John Murphy to take charge of operations which are planned to begin within a month. The Ontario-Kirkland is nearly ready to resume operations. About 1000 ft. of lateral work has been done on the 300-ft. level and several good veins cut. Two shoots of ore 200 ft. and 100 ft. long and 5 ft. wide carry high-grade ore. The Kirkland Combine shaft is down 150 ft. Four parallel veins cut by diamond-drilling will be developed on the 250-ft. level.

ALASKA

Hyder.—O. B. Bush of Vancouver has purchased the Glacier group, on the Canadian side of the international line, and the Gray Dawn group, adjoining the Glacier, but on the Alaska side. The first consists of eight claims and fractions and is situated just west of the Indian Mines group. There has been practically no work done on the property as it was located only last summer. The owners were William Hedges, William Jancowski, H. S. Scovill, and Harry Reid. It is understood that Mr. Bush will incorporate a company to operate, and that the vendors will receive from him a cash consideration and a certain amount of stock. The Gray Dawn group consists of seven claims also of recent location. Both are well situated and Mr. Bush will prove next summer what their value may be. The vendor of the Gray Dawn is H. H. Howard.

ARIZONA

Superior.—The Silver King of Arizona Mining Co. reports that the new shaft had been completed to the 616-ft. level, where a vein was intercepted assaying 188 oz. silver per ton. In the No. 3 east stope, 40 ft. from the old workings in virgin ground and 70 ft. above the 400-ft. level, a new body of ore has been found which is 10 ft. wide and assays 25.8 oz. silver.

CALIFORNIA

Grass Valley.—The south cross-cut from the 400-ft. level of the Alcalde mine has opened a shoot of ore showing free gold. Work has begun to determine extent of this orebody. The property was formerly known as the Kenosha and produced a considerable quantity of high-grade ore. Milling ore is exposed and the mill is to go into operation at an early date. Lloyd Root is superintendent. The Coe mine has been sold for taxes to L. P. LaRue of Grass Valley for \$1025.

Nevada County.—The Red Ledge company, operating near Washington under the management of Lewis Hind, has started to extend the lower tunnel into the ore-shoot. The tunnel is more than 900 ft. long and it is estimated that another 300 ft. will cut the rich vein found in the upper levels. An important strike has been made in the Kenosha on the 400-ft. level. A blast disclosed a 3-ft. vein of quartz sprinkled with free gold. W. H. Martin of Nevada City has purchased the Celia, Free Trade, and Red Cross group near Omega at a delinquent tax sale, for \$1389. The property is equipped with a 20-stamp mill and other machinery.

Oroville.—Several new hydraulic properties will be in operation east of here within a few weeks.

At Scales, the old Council Hill property is expected to resume under the management and control of H. L. Berkey, while over in the Gravel Range and a few miles south-west from Buck's ranch, the Old Channel mine will be running monitors under the direction of B. S. Taylor.

At Spanish ranch, in Plumas county, the Australia Placer Co., in which Carl Wolfe and Henry Orr are interested, has built a retaining dam according to Federal specifications, and flumes will soon be carrying tailing from the mine, depositing it behind the new barrier in Waupanese creek.

H. J. Greenbower will hydraulic at the Mt. Ararat mine

near Buck's ranch, and G. W. Fagg of the Gold Mountain Hydraulic expects another remunerative season despite the light snowfall to date.

Quincy.—The Onion Valley Mining Co. has arranged to resume work on its properties in Onion valley. Approximately 2800 ft. of tunnels already has been driven. W. A. Hunter is resident manager.

Spanish Ranch.—The Australia Placer Co. has erected a restraining barrier on Waupanese creek and is preparing for large-scale work. An extensive deposit of gold-bearing gravel is exposed and the property is well equipped.

IDAHO

Coeur d'Alene.—The Hecla Mining Co. has declared a dividend of 15c. per share, totaling \$150,000, to be paid March 28 to stockholders of record at the close of business March 1. This payment will make the total amount of dividends \$8,005,000.

MISSOURI

Barry County.—The contract for construction work on the Silver Lake Mining Co.'s \$1,000,000 'cyanide process' reduction plant at Seligman, has been awarded, according to word received in Joplin. Work will be started within a short time on the actual construction of the plant, which means the opening of a new mining district in south-west Missouri.

MONTANA

Butte.—Daily shipments of manganese ore are being made by the Anaconda company from the Emma mine of the Butte Copper & Zinc Co. to the ferro-manganese plant at Great Falls. Ferro-manganese at the present time is selling at \$140 per ton with the demand good. Shipments of 100 tons per day are being made and 40 tons of ferro-alloy is produced. A tonnage of manganese ore has been blocked out at the Emma mine, larger than can be found in any other property in the United States. Recently a silver-zinc orebody was opened at the Emma mine which now has a width of 17 ft. Anaconda is driving south from the Emma to connect with the workings of the old Ophir mine.

NEW MEXICO

Hanover.—The Empire Zinc Co. has purchased the entire capital stock of the Republic Mining & Milling Co. at \$1.25 per share. This brings the amount paid for the mine to just over half a million dollars. The property transferred consists of two groups and a single claim all lying close to the Hanover property of the Empire Zinc Co. There is the Welch group containing 90 acres, the Abrahamson group containing 175 acres, and the Silver Dollar containing 17 acres. The property is opened by three shafts and to a depth of 200 ft. All these shafts are in ore. The outstanding feature of the mine is a body of high-grade zinc ore which was cut recently in a drift on the 150-ft. level of the No. 1 shaft and about 90 ft. from the shaft.

OKLAHOMA

Picher.—The Hunt Mining Co. is preparing to erect a larger and better mill than the one known as the Pittsburg-Miami that was recently destroyed by fire, and work will be started as soon as insurance adjustments have been made. The company owns several other properties in the Kansas-Oklahoma field, all under the management of C. C. Whittier.

UTAH

Salt Lake City.—During 1919 the Utah Copper Co. mined 5,661,941 tons of ore, from which was produced 28,907 oz. gold, 263,721 oz. silver, and 105,088,740 lb. of copper, the gross value of which was \$19,554,541. The cost of production and construction items amounted to \$13,518,508, leaving net proceeds of \$6,036,033, as against \$13,891,522 in 1918. The total amount of dividends paid during 1919 was \$9,746,940. —The itinerary of the Bureau of Mines car No. 11, assigned to the intermountain district for instruction of miners in first-aid and in mine-rescue work for the period from February 22 to May 1 follows: Wendover, Utah, February 22 to 28; McGill, Nevada, March 1 to 13; Ely, March 15 to 20; Kimberly, March 22 to 27; Elko, March 29 to April 3; Eureka, April 5 to 17; Battle Mountain, April 19 to 24; Austin, April 26 to May 1.

WASHINGTON

Spokane.—At its closing session on February 20, the Northwest Mining convention adopted, after two days of discussion, a resolution which virtually admitted inability to solve the gold situation. Part of the text follows:

"Whereas, Owing to the world war, the ratio between national and international credits and metallic reserves has far exceeded the limit of safety; and

"Whereas, The production of gold, the world's metallic standard of value, cannot be profitably carried on under present conditions in quantity sufficient to maintain the world's metallic reserves; and

"Whereas, There is a wide difference of opinion as to how the market value of gold may be increased to the point of profitable production; and . . .

"Be it resolved, That the Northwest Mining convention, assembled at Spokane, Washington, February 16-21, 1920, and representing the States of Montana, Idaho, Washington, and Oregon, and the Province of British Columbia, hereby urges and petitions the President of the United States to call forthwith and by proper procedure a conference of qualified international experts for the express purpose of devising ways and means of safeguarding the world's credits by increasing the world's metallic reserves of gold, or by such other expedients as may be deemed safe and certain; and

"Be it further resolved, That as a temporary expedient to preserve the gold-mining industry until such international conference has arrived at a permanent solution we endorse the resolutions adopted by the American Mining Congress at St. Louis, November 1919, asking for a premium of \$10 per ounce upon new gold, such premium to be raised in part by an excise tax of the same amount per ounce upon all gold used in the arts or for other than monetary purposes."

ONTARIO

Cobalt.—Three shipments of silver bullion were made to Shanghai, China, last week valued at \$405,130. This is the richest consignment ever sent out in one week. They comprised 200,168 oz. from the Nipissing and 100,388 oz. from the Mining Corporation of Canada. The annual report of the Temiskaming shows a production of 243,037 oz. of silver, compared with 420,078 oz. in 1918. Earnings were \$295,252 as compared with \$425,014. The surplus for the year was \$70,448 and the total surplus \$993,186. Operating costs averaged \$15.61 per ton milled. —The Kerr Lake during January produced 108,000 oz. of silver.

SALVADOR

For some time the Butters Divisadero Co. has been negotiating for an operating agreement or the outright acquisition of the Mina de Encuentros. Nothing was accomplished, however, and the Encuentros mine is now free of all option liens and purchase contracts. The original owners, sons of Felipe Macay, are operating the mine as before the mentioned negotiation.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

J. C. Ray is on his way to Butte, Montana.

R. C. Gemmell and **L. S. Cates** are in New York.

W. J. Loring has been on a visit to Grass Valley.

John Smeddie is on his way to Guanajuato, Mexico.

Frank C. Loring has returned from London to Toronto.

J. M. Sully, general manager for the Chino Copper Co. in New Mexico, has gone to New York.

Adelrich Benziger, recently with the Seoul Mining Co., in Korea, has returned to New York.

A. E. Drucker has been appointed professor of metallurgy at the Wisconsin State School of Mines.

Lewis A. Parsons, associate editor of the 'M. & S. P.', is at Jerome; he will go later to Ajo, Arizona.

H. A. Kursell, manager for the Altai Mines, Ltd., passed through San Francisco on his way to London.

Solon Spiro, president of the Silver King Consolidated Mining Co. at Park City, Utah, is in New York.

Julius Kruttschnitt, Jr., consulting engineer to the A. S. & R. Co., is examining mines in Sinaloa, Mexico.

George Kingdon, superintendent of the U. V. X. mine, at Jerome, is undergoing treatment at Rochester, Minnesota.

Y. Fukihara and **H. Nakamoto**, both of the Mitsubishi Mining Co., are visiting mines and smelters in the South-West.

Lu-Cheng Chiang, a graduate of the Colorado School of Mines, sailed on the 'Nanking' on his way home, last Saturday.

C. W. Whitley, vice-president of the A. S. & R. Co., is making a tour of inspection of the company's smelters in Utah.

H. R. Robbins has been appointed mill-superintendent for the Hanover Bessemer Iron & Copper Co. at Fierro, New Mexico.

C. C. Gordon, who has been spending the winter at Salt Lake City, has gone to Bolivia and Chile on professional business.

H. S. Munroe, general manager for the Consolidated Coppermines Co., at Kimberly, Nevada, was in San Francisco this week.

Charles B. Croner has returned to Los Angeles, after spending some time with the Natomas Dredging Co. to study their dredging methods.

E. C. Montgomery has resigned as superintendent of the Kate Hardy mine at Forest to take over and open up a mine near Auburn, in Placer county.

N. P. Nissen, Lieutenant-Colonel B. E. F., addressed the Engineering Society of Queen's University on January 30, describing the Nissen hut, which he invented.

A. M. McDermott sailed on the 'Mazatlan' on February 16 for Choix, in Sinaloa, Mexico, where he will have his headquarters as general manager for the El Fuerte Mining & Smelting Co.

Obituary

George Z. Edwards, a well-known mining engineer of Utah, and a resident of Salt Lake City for 25 years, died at his home on February 16. For a number of years he was identified with the Dern mining interests at Mercur, and recently has been acting as superintendent of the Lynn Big Six property at Carlin, Nevada. He was a native of Pennsylvania, and before coming to Utah was engaged in mining in Colorado and Montana.

EASTERN METAL MARKET

(By wire from New York)

February 23—Copper is more active and firm. Lead is active and stronger. Zinc is active and higher.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½, on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.45 pence per ounce (925 fine), calculated at the normal rate of exchange.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

MONEY AND EXCHANGE

In discussion of the new railroad law agreed upon by the House and Senate conference committee and likely to be enacted before March 1 without extensive changes, it has been assumed that the commission law upon property accounts of carriers as test of their investment. The law leaves to the commission the determination of the investment, without specifying either the accounts of the carriers or the valuation process being conducted by a bureau of the commission and now approaching completion. Omission of any stated measure of valuation was not accidental. It was the purpose of the framers of the law to leave the commission free to use whatever measure of the investment value it saw fit and to reach its own conclusions from all evidence available. The result is that the commission will be in a position to make use of the partial results of valuation, at least as testing roughly the validity of the carriers' accounts, whereas if the law were to base the rate-making process expressly upon physical valuations to be found, it would be unworkable until these valuations had been completed or until they had been passed upon by the courts. It is possible the commission will adopt aggregate book values of the properties in a given rate-making region as basis upon which to adjust rates and judge sufficiency of net revenues, pending the completion of valuation.

It is just this point that is likely to have an important bearing upon the much-discussed provision for the division of excess earnings of the stronger roads. Eventually, if not at once, the commission will have to adopt the official valuations of the respective carriers as the base upon which to allow a free and undivided return of 6%. As roads of comparatively large net property earnings are those of low capitalization and correspondingly low property accounts, they are necessarily the roads which will show up best in valuation. In other words, a road which appears to come under the profit-sharing provision of the law when judged by the returns on its property account may not do so when judged by the rate of return shown on the appraised value of its property.

As to the general rule according to which the commission is directed to adjust passenger and freight rates, it seems practically certain to afford more liberal revenues than the roads have had for the past ten or fifteen years. Assuming that in the aggregate the investment upon which a return of 3½% with a discretionary additional ½% for uncanceled improvements, is to be not less than the property account as of the present time, some idea of what it means may be gathered from the following record of the percentage return on the "book cost of the property" for all the railroads of the United States:

Eastern Metal Market

New York, February 18.

All the markets are quiet to moderately active. The more stable conditions prevailing in foreign exchange have been a factor making for firmer prices.

Copper demand is light but prices are unchanged.

The tin market has been very quiet but fluctuations in prices have been less erratic.

Demand for lead is moderate and prices are, if anything, firmer.

Inquiry for zinc is better and quotations are slightly higher and firmer.

Antimony has experienced a slight advance.

IRON AND STEEL

Insistent pressure from buyers, together with small stocks in the hands of consumers are the features of the market. The hand of cautious finance has shown itself in various ways. The volume of business has tapered off, due almost entirely to the refusal of mills to entertain orders. Price advances are still reported but this is not general. The trade is convinced apparently that, if a setback takes place, it will be of short duration. The January steel output, according to the American Iron and Steel Institute, was at the rate of 40,796,652 gross tons per year, or 84½% of the best rate in 1918 and probably 83½% of total capacity. February output will show a marked decline.

The Chicago district stands out in pig-iron buying activity. Prices of Eastern iron ore have been fixed to correspond with the recent Lake-ore advance of \$1 per ton. Railroad inquiries are developing. Car shortage is still a serious drawback. In tin-plate probably 1,000,000 boxes are piled in mill warehouses in Pittsburgh awaiting shipment.

COPPER

The market is exceedingly quiet but values are practically unchanged. After the heavy buying in December and early January interest in the market has materially subsided. So far as export business is concerned the exchange situation has eliminated it. The major or producers' market is quoted at 19c., New York, for electrolytic for early or first-quarter delivery with second quarter at 19.25c. For Lake copper 1c. above these levels rules. In the outside market quotations as low as 18.50 to 18.75c., New York, for early-delivery electrolytic are noted, but not much metal is available. Producers are confidently looking forward to a more active market, both for domestic and foreign account, in the near future.

TIN

Consumers have been inclined to remain out of the market, which has been and is very quiet. Only a moderate amount of trading is reported, all in spot, with dealers the principal participants. It is evident from the course of the market that spot-supplies are being concentrated and that some strong interests are piling up reserves. Sellers who were pressing the market only a short time ago are not doing so now. On February 16 the market experienced its most active day of the week, there being a fairly brisk demand. Whether this resulted in much business or not is not definitely known yet, buyers in general being chary. Early that day spot Straits sold at 59.75c., but late in the day this position had declined to 59.25c. The following day spot Straits was quoted at 60c., New York. The more stable exchange situation has caused less unsettlement in prices here. There has been practically no business in future shipment. Arrivals thus far this month have been 2670 tons, of which only 150 tons is credited to Pacific ports. Tin afloat is reported as 5445 tons. The London market continues

strong, spot Straits having been quoted yesterday at £392 per ton.

LEAD

This market is very quiet, but if anything prices are firmer though actually unchanged at 8.75c., New York, or 8.50c., St. Louis, for both the leading interest and the outside market. The tendency in the latter is upward and some sellers are asking 8.80c. to 8.85c., New York, with spot strong at close at 9c., New York. Demand is light and requirements filled.

ZINC

This market while quiet is firmer, due to the steadier conditions in foreign exchange and to a better domestic inquiry. Both galvanizers and brass-makers are asking for early-delivery zinc and their demands have been fairly plentiful the last day or so. This has resulted in some business. Producers expect these consumers to be actively interested before long in metal for the second quarter. Prime Western for early and first-quarter delivery is quoted at 8.75c., St. Louis, or 9.10c., New York, the same price being quoted by some for April delivery.

ANTIMONY

The market is strong with wholesale lots for early delivery quoted at 11.62½c., New York, duty paid, against 11.50c. last week.

ALUMINUM

Wholesale lots of virgin metal, 98 to 99% pure, for early delivery, are quoted from 31c. to 33c. per pound, New York, depending on the seller and delivery.

ORES

Tungsten: The Senate Finance Committee has taken action on the tariff matter. It has recommended that there be eliminated from the house bill the provision that there shall be levied on all tungsten or concentrates, that have been imported prior to the passage of the act, when such ore has been purchased at a price less than \$17 per unit of tungsten tri-oxide therein contained, a tax equal to the difference between the purchase price and that amount. The bill provides a duty of \$10 per unit on ores and concentrates and one of \$1.50 per pound of tungsten in high-speed and alloy steel and ferro-alloys.

Molybdenum: The market is quiet and quotations are quoted as purely nominal at 75c. per pound of MoS₂ in 90% concentrates.

Manganese: The market is strong with ore scarce and in demand, as high as \$1 per unit being asked for high-grade foreign ore.

Manganese-Iron Alloys: Carload lots of domestic ferro-manganese have sold up to \$180, delivered, over a period of 60 days. This contrasts with \$175 to \$185 paid for spot alloy. The market is strong, the preponderance of inquiry coming from those needing alloy for early or spot delivery, which is scarce. Domestic producers are asking \$160, delivered, for second-half and the relatively small amount of British alloy that is available, is held at not less than \$155, seaboard. Spiegeleisen is higher at \$57 to \$60, furnace. Sales of moderate amount of both alloys have been recently recorded.

Charles Hardy, Inc., of New York, states that while nominally quoted at \$80 per flask, quicksilver does not seem to be available at this figure and that there is no difficulty in obtaining a premium for spot delivery. The nominal quotation for chrome ore remains at 75c. per unit, with supplies for early deliveries very scarce.

T. A. RICKARD, . . . Editor

WE are requested to draw attention to a typographical error in the front-cover advertisement of the Dorr Company in our issue of February 14. The capacity of the 15-ft. Dorr bowl classifier at the Golden Cycle mill, at Cripple, Colorado, is 1300 tons daily, *not* 300 tons, as stated in the advertisement.

SIMP SPELLING has been rejected by the members of the Institute, we are glad to say. The recent vote went against the proposal brought forward by Mr. Shockley and his friends. We are glad of it, and hope now that, like good Americans, they will accept the vote of the majority and cease to trouble us further with their vagaries. Incidentally, is it too much to ask that the secretary of the local Section accept the decision of the Institute and drop sundry eccentricities of spelling that have annoyed many of us in San Francisco?

IN these days when the aftermath of war makes life so uncomfortable and perplexing, when the fruits of victory taste like Dead Sea apples, and the future is so overcast, we feel keen sympathy with the colored gentleman, wearing military uniform, who exclaimed: "I enlisted for the duration of the War, and the War am over, but I'se still in the Army." His comrade replied, "Yes, you 'listed for de War, and de War am over, but the duration am just beginnin'." It's the "duration" that hurts!

ONE week last month silver producers at Cobalt credited themselves with \$622,444 as proceeds from the sale of a trifle more than 400,000 oz. of fine metal; this being at the rate of approximately \$1.55 per ounce in Canadian currency. This exceptional price is calculated on the current American market quotation, and the co-incidental premium of 15% on exchange at New York, where the financial part of these transactions is arranged. The identical bullion if marketed six years ago would have netted the vendors less than \$200,000. Incidentally, this particular shipment was consigned direct to the Orient, principally to China.

FROM the mines at Unsan, Korea, comes the report that the price of native foodstuffs and clothing continues to advance and that in consequence the management has increased the minimum wage to 50 sen per day, with a bonus of 10 sen per day for all miners who work 25 days or more during a month. Board and lodging cost 12 yen, so that a Korean who receives 15 yen per month

has a surplus of 3 yen, which is barely sufficient to buy shoes and clothing. One yen is equivalent to a half-dollar. We can understand how \$6 worth of rice will go a long way toward maintaining a tolerably full stomach, but it seems certain that the Korean taste in shoes, haberdashery, and tailoring cannot be exuberant. Mine managers at home may find some degree of consolation in learning that the difficulties arising from the increased cost of labor are paralleled in the remotest corners of the earth.

ON another page we tell of the measures taken by the mine operators of the Witwatersrand in forestalling disaffection among the native employees of the mines. A marked similarity between the difficulties experienced by the South African companies and those faced by operators in our own country is worthy of note. Self-appointed native leaders, too well educated to work themselves, agitate the mine-workers to a point where they feel abused; they demand more wages, and trouble follows. In this case, however, the Native Recruiting Corporation, which supplies the labor for many of the mines, solved the problem, for the time being at least, by calling a congress at Johannesburg of the native chiefs and headmen from all over the Transvaal. This meeting averted trouble temporarily, but the operators do not feel at all secure as to the duration of the settlement.

LAST week we outlined the main features of the Mineral Land Leasing Bill, which has in the interim been signed by the President and become law. At various places in Wyoming, Utah, and elsewhere there was some competition among engineers, who were on the spot waiting for official announcement that the Act was in effect, to be the first to post notices on particularly favorable areas. The law provides for a period of 30 days after posting during which application for permits to prospect may be filed. Some misapprehension prevails as to the character of the land that had been withdrawn and is now released. The impression that the territory is proved oil-land and that it is only necessary to get a permit, start a drilling-rig, and make arrangements to dispose of an assured output of crude oil is wrong. Much of the land thrown open is classed as 'doubtful' by the U. S. Geological Survey and most of the remainder, while bearing indications of the probable occurrence of oil, is undeveloped as yet. The Naval Reserve oil-lands in Wyoming and California, amounting to 100,000 acres, are not re-

leased for prospecting at the present time. The immediate result of the Act as far as oil is concerned probably will be an increase of from 3 to 5 million barrels in the annual production of Wyoming and a somewhat larger increase in that of California. An interesting fact in connection with the measure is the prominent position of Wyoming in respect of all the resources affected; this State rivals California in the extent and value of oil and gas lands released; it far outstrips all other States in the value of coal deposits affected by this Act and appraised by the Government; it has extensive oil shale areas; and is second only to Idaho in the extent and richness of its phosphate deposits.

BRYAN is against Hoover; so is Boies Penrose; so is Sam Untermyer; and Hearst too, thank Heaven! Here are four good reasons for electing him! Three of these are Democratic, and we confess that we had cherished the hope that the Democrats would nominate him. Apparently this is unlikely if the machine has its way. Perhaps it won't. We note that Mr. Hoover declined to have his name filed as a Presidential candidate in the Georgian primaries and that he said: "I was not identified with the Democratic party before the War, and my official connection with the Government has been solely a war service, and consequently not of a partisan character." In short, he refuses to make any claim to the suffrage of the Democrats on account of anything he may have done as Food Administrator. He voted for McKinley and he supported Roosevelt ardently. Is he therefore a Republican? He may be; but not of the stand-pat or reactionary type. He is no more in accord with the old guard of one party than with the frothy element in the other. Shall we blame him? Are not most of us disgusted with the dominant elements of both parties, and are we not looking for a leader that will take us from the jungle of the emblematic elephant and the equally emblematic donkey into the open country of real statesmanship and genuine Americanism?

EXCHANGE has many facets. Recently the dollar was worth 6 shillings, instead of 4, in London, so that the 20 shillings in the pound was equivalent to 13½ shillings in New York, but at that time the pound was worth 39 shillings at Paris and nearly as much at Brussels, while at Rome its purchasing power was 31 shillings, and at Berlin as much as 325 shillings. No wonder, therefore, that great bargains could be made by buying things in Germany, although the authorities there have now insisted in certain cases on payment in the currency of the buyer. Gold went to 129 shillings and silver to 88 pence in London. To get the price in cents at normal exchange, multiply one by 25 and the other by 2. The Canadian government is paying for gold in New York exchange, thereby giving the Canadian miner a premium of 15%. The silver miner is equally benefited, so that he gets \$1.55 per ounce for his silver. Meanwhile our friends in South Africa are jubilant over the turn of events, which has had the effect of giving them a

premium of nearly 50% on their gold. We congratulate them: it was about time for a turn in their luck. India, South America, and even South Africa are buying gold in New York, the last making purchases for coinage, the previous gold coinage having been melted down owing to the premium offered on the metal. This illustrates the extraordinary condition of international monetary affairs.

Mr. Hoover and the Republicans

We have received a letter from a mining engineer at Los Angeles saying that he and his Republican friends would like to know, "whether Mr. Hoover at one time came out with an announcement to the effect that Democratic congressmen should be returned to Congress in support of the President." The facts are these. On October 28, 1918, on the eve of the Congressional elections, President Wilson made an appeal to his "fellow-countrymen". He said: "If you have approved of my leadership and wish me to continue to be your unembarrassed spokesman in affairs at home and abroad, I earnestly beg that you will express yourselves unmistakably to that effect by returning a Democratic majority to both the Senate and the House of Representatives." The President proceeded to declare that although no party had a monopoly of patriotism, "a Republican Congress would divide the leadership", because the Republican leaders, even though they had been for the War, had been opposed to his administration. "At almost every turn since we entered the war, they have sought to take the choice of policy and the conduct of the war out of my hands. . . . The return of a Republican majority to either house of the Congress would, moreover, be interpreted on the other side of the water as a repudiation of my leadership." The country did return a Republican majority to both houses of Congress and the leadership of Mr. Wilson was repudiated, unfortunately for him personally and unfortunately for issues even bigger than his personal prestige. Although the election went against him, he went back to Paris and entered into a number of engagements with the representatives of other countries, engagements that he has been unable to make good because the Senate has declined to confirm them. He did not receive the vote of confidence for which he asked, the European leaders did not realize the fact sufficiently, and the consequence is that they made a peace on terms that their national legislatures ratified, but the American Senate did not, so that the efforts to arrive at a post-war settlement of international affairs have lapsed into bewilderment and confusion. But what did Mr. Hoover say? He is nothing if not loyal. He had become a member of the President's official family, as it were. He was invited to support the President in his appeal to the electorate, and he did not hesitate to do so, although manifestly it was poor politics, as politics are understood by the mere politician. He wrote: "My own views are summarized in a word—that we must have united support for the President. In the issues before us there can be no party politics. It is vital that we have a united

front and a sustained leadership." In short, he did not second the partisan appeal of the President, but he did ask the people to give the Chief Executive the expression of support he required for the performance of his work as their representative at Paris. The Armistice was not then assured; the end of the War seemed near, but there was much to be done; it appeared necessary to back the President during the remainder of the War and in the impending negotiations for peace. We say deliberately, no matter how repellant the egoism and vanity of Mr. Wilson may be, and however great his manifest failure to rise to a superb opportunity, that it would have been better, for our own country and for the world at large, if the President had received the support of a friendly majority in Congress, and therefore we accept Mr. Hoover's action as evidence of a fine personal loyalty and a large patriotic sagacity.

Concerning Metal Quotations

"Bang! went the boy-scout's trusty rifle, and the redskin jumped fifty feet into the air, never to come down again." Please excuse this echo from our school-boy's reading; it is prompted by a similar outburst, introducing a letter in a recent issue of our contemporary in New York. It appears that Mr. P. B. McDonald wrote to the *'Engineering and Mining Journal'* conveying his compliments on the "nerve" of the New York paper in expressing "surprise that anyone should have the impression that the 'E. & M. J.' is 'allied with Wall Street and the Trusts'". This last phrase is quoted from our contemporary's issue of February 7. Mr. McDonald's letter is not printed under the heading he expected but under a humorous reference to the redskin of dime romance. That was funny, whereas Mr. McDonald evidently was very serious in attacking the 'E. & M. J.' for "a certain reactionary and capitalistic aloofness" and for its "obvious bias" toward malefactors of great wealth. We are glad he did not send the letter to us for publication, because we, of course, could not have allowed anything so unkind to be printed in our pages, however much we might be in accord with Mr. McDonald. Indeed, while we do not believe that the 'E. & M. J.' is the tool of the 'trusts', even the smelter trust, or of any other bold bad people, we do think that our contemporary feels the influence of propinquity. It is only human to be friends with your neighbors. Environment counts more heavily than heredity. A spirit friendly to its neighbors at 120 Broadway pervades the editorial on the metal market appearing in the issue that contains Mr. McDonald's letter. Our contemporary sighs to transfer "the burden of being the quoter of the most reliable figures" on metal prices to an exchange or some other old thing. The job is so tough. We sympathize with the editor, for it is extremely unlikely that anybody will do the statistical guessing even as well as Mr. Ingalls, who recently retired from the editorship and who gave so much of his time to this unpleasant task. The distinguished geologist who is now editor says that "a public

exchange would mean the turning over of the metal industry to middlemen and speculators . . . it would mean corners and combinations by influences unseen and unknown, and therefore the skimming and starving of the producer and the consumer alike, for the better clothing and fattening of the parasitic class". Too many words, Mr. Editor. As if combinations did not now establish the quotations for the base metals and as if the alliterative ill treatment of the small producer was not now a matter of personal knowledge and public resentment. The gentleman in New York has detected no signs of displeasure among the miners; it is true, complaints are made by the farmers, but not by those engaged in mining; there contentment reigns. "In the mining industry we hear little or nothing of real or fictitious Bolshevism", says he, because "the metal industries are, in part at least, on an ideal and bedrock basis, which even the Socialists could hardly show us how to improve." Then in the name of Sincerity who has been writing those Hearst-like vaporings on Bolshevism that have appeared in large print across the upper half of the first editorial page of the *'Engineering and Mining Journal'*? Indeed, Mr. McDonald did bring down something that looks like a cigar Indian. The self-complacency of the *'Engineering and Mining Journal'* over its metal quotations is amusing, having regard to its own ingenuous confession, appearing in the issue of February 7. Let us quote the paragraph to which Mr. McDonald refers: "We have encountered a certain feeling that the McGraw-Hill Publishing Co., which publishes the *Engineering and Mining Journal* and ten other publications, and which, through its allied company, the McGraw-Hill Book Co., is the largest publisher of technical books in New York, is allied with 'Wall Street and the Trusts', and that the metal quotations of this company are controlled by the great metal-producing companies." What the number of publications, even though it be so overpowering as eleven, has to do with the accuracy of metal quotations, we do not know. However, it throws a light upon their discrepancies, as we are duly informed, for the editor of one of them proceeds to show how his unimpeachable statistics differ from those given by the other editors of this journalistic phalanx. Let us quote him again: "We find that, of three of the technical journals published by the McGraw-Hill company, the *Engineering and Mining Journal*, *Chemical and Metallurgical Engineering*, and the *Electrical World*, all of which publish New York metal quotations weekly, no two agree. For example, on Jan. 6, the *Electrical World* quoted copper 19 $\frac{1}{2}$ a 19 $\frac{1}{2}$ c, and tin 63.25c. On the same day the *Engineering and Mining Journal* quoted copper 18.85a 19.10c., and tin 61 $\frac{1}{2}$ c. *Chemical and Metallurgical Engineering* on Jan. 5 quoted copper 19 $\frac{1}{2}$ c., lead 8.00c., zinc, East St. Louis, 9.27 $\frac{1}{2}$ c., and on the same day the *Engineering and Mining Journal* quoted copper 18.85a 19.10c., New York lead 8.45a 8.55c., and zinc, East St. Louis, 9.35c. Comparisons on other dates are correspondingly dissimilar in nearly all cases." In short, the 'E. & M. J.' quotations for copper, lead, and tin differed by $\frac{3}{4}$, 1 $\frac{1}{4}$ cents

per pound, respectively, from those appearing on the same day in other papers owned by the same syndicate. The editor proceeds to say: "Certainly we must exonerate the McGraw-Hill company of systematic collusion with anything or anybody, even with itself, in the past; but in the future 'The Journal' will try to secure a greater uniformity of metal quotations among those different journals at least." By all means, gentlemen, get together! We exonerate you of systematic collusion, and we acquit you of systematic accuracy.

Human and Humane

In this issue we publish the text of a paper read last week before the local section of the Institute by Mr. Edwin Higgins. The subject was the treatment of employees at mines and mills; it may be termed the human or humane aspect of mine economics. Mr. Higgins is well qualified to discuss this important matter, for to careful observation he joins the sincerity without which no discussion on vital matters is worth while. He was addressing mining engineers, therefore he discussed the attitude of the employer; naturally, if he had been talking to employees he would not have laid so much emphasis on the idea of getting more out of the men. One of the subsequent speakers suggested that whereas the engineer used his skill in exploiting valuable natural resources, he failed to exploit the resources most valuable to industry, namely, man. Another dwelt eloquently on schemes for making the men comfortable and happy. Those are the ways, of course, that discussion on the subject usually goes. Both are unlikely to fulfil their purpose. No man likes to think of himself as being exploited for the benefit of others; much of the so-called welfare work fails simply because the objects of it become self-conscious, they resent the idea of being bamboozled by kindness into becoming more effective machines for money-making by capitalists; they detect the cant that lurks in much of the pseudo-philanthropy of captains of industry. On the other hand, the Sunday-school sentiments of some managers and superintendents are hardly less liked than the frank commercializing of beneficence; it is obvious to anyone but a fool that the object of mining is to make money, not to give men reading-rooms or shower-baths; the purpose is to turn ore into dollars, not to Americanize aliens or placate potential I. W. Ws. An owner that heard the superintendent of his mine protesting that he was only running the mine in order to render the community happy would be wise in ridding himself of a representative that was either a knave or a chump. Let us shed all sloppy sentiment and come to realities. The purpose of mining is to make money; how can it be done humanely but effectively? How can we set aside the crude idea of exploiting men as if they were machines and yet avoid insincerities concerning our purpose in paying proper regard to their health and contentment? We think it can be done by aiming to win their loyalty; loyalty from them ensures co-operation and honest labor; loyalty to them will prompt regard for their well-being; the loyalty must be mutual. If the manager endeavors to

cultivate a spirit of loyalty in his men, he will get all the rest for which he aims. Loyalty calls for continuity of employment. The curse of mine labor is its intermittence; intervals of idleness dissipate the small savings that the miner makes; they incite migration, which is costly. To develop loyalty it is necessary to retain men long enough to become well acquainted with them and to cause them to feel themselves a part of the mine community. That suggests some scheme of housing such as will cause a good type of men to take domestic root in the locality. The appreciation of good service will lead the management to take an interest in the lives of its employees and therefore to provide for them, preferably indirectly, facilities for recreation. Above everything, the suggestion of patronage must be shunned. It is best to let the men take the initiative and then assist them. For that purpose workmen's committees are useful, for they render the employees articulate, thereby creating a link of communication that will go far in assisting a mutuality of understanding. The short life of many mines prevents the development of any systematic policy, but, on the other hand, the smallness of a mine affords a closer contact between manager and men than is possible in the big enterprises, which suffer the penalty of their bigness, namely, the delegation of authority to many subordinates and the necessary indirection of an elaborate organization. The choice of shift-bosses is important. Tough Irishmen armed with pick-handles might serve Marcus Daly in the early days of Butte, but all that ignorant brutality is out of date. Today college graduates possessed of a physique strong enough to go through the apprenticeship of drilling, shoveling, and timbering, make the best shift-bosses. Until a man has felt the pain between his shoulder-blades that comes of manual toil, he is not in a position to understand the toiler; to have done the work himself makes a man a fairer judge of another man's work. Educated men treat the uneducated better than their own kind; there is more humanity, as well as more intelligence, in a graduate of Berkeley or Houghton than in one of Daly's Hibernians. Another suggestion: many a mine has had labor troubles on account of its boarding-house or its store. Don't sacrifice the economies of a mine to the profiteering of the boarding-house or to the gain from store-keeping. Neither of them should be a source of profit; both of them should be conveniences conducive to contentment. To feed workmen inadequately or unwholesomely is as foolish as to send waste to the mill; to run a store in order to get back a part of the men's wages is no wiser than making a rich tailing for the sake of re-treatment. In all these relationships of man to man there must be an ideal of fair play—of the 'square deal' as Mr. Higgins says. It is not easy to establish it among a migratory and an alien proletariat, such as has replaced the labor of an earlier day; but it is at least a satisfaction to a good American to remember that if he succeed in establishing that ideal of fair dealing, and then of loyalty, he will be assisting the great process of Americanization on which the welfare of this republic must rest.

DISCUSSION

Blue-Sky Laws

The Editor:

Sir—Regarding wild-eats and Blue-Sky laws: It is most desirable to prevent fraud, and any law that will effectively prevent fraud is one which all good men will support, regardless of the cost of administering such a law. The main opposition to Blue Sky laws springs from the feeling that they do not prevent fraud, and, on the other hand, it is admitted that they are a burden upon legitimate industry.

There is a good deal of basis for this feeling. I think it was Solomon who said "A fool and his money are soon parted." Solomon was a wise ruler, but he evidently could devise no law that would prevent a fool from parting with his money. It does not yet appear that our modern law-makers have accomplished what Solomon failed to do. I have operated in several States having very rigid Blue Sky laws, but have never observed that a fool had any more trouble in parting with his money under Blue Sky regulations than without such regulations.

Consider the matter from the standpoint of the 'wild-eater'. Let us imagine, Mr. Editor, for the sake of argument, that you and I are accomplished 'con.' men, and that we are planning a line of activity. To what extent will a Blue Sky law retard us? Now I venture to say there are ten thousand avenues of industry open to our refined talents, and a Blue Sky law has to do with only one of these avenues. It does not even block that one. By carefully studying the law, we may twist it to our nefarious uses. I have seen it done. The point that I wish to make is that Blue Sky laws, at best, make only one strong panel in a fence that must have ten thousand such panels if it is to be effective against 'wild-eats'.

Blue Sky laws, together with a large proportion of the laws inspired by our modern reformers, are a nuisance and an irritation to the man 'who can do things'. By far the most serious strike that is in progress today is the silent strike of the men 'who can do things'. The big men are quitting. They have no union and no loud-mouthed walking delegates, but they are quietly winding up their affairs and dropping their tools. I see it wherever I go. Our captains of industry have been harassed with legislation, political dictation, red tape, arbitrary taxation of effort, as well as of money, until the incentive to intense individual effort is gone. To my mind no strike of recent times is half so portentous as the unheralded strike of the men 'who can do things'.

Is it not about time to give some thought and attention

to the "working conditions", the "hours of labor", and "healthful recreation" of our captains of industry, when so much thought and attention is bestowed on these subjects in connection with day's-pay men? So in framing, amending, or administering Blue Sky laws it seems to me that it should be borne in mind that at best such laws can do very little good, and, hence, they should work as little bother to the legitimate operator as is possible.

An old mining friend of mine was discussing the matter in a whimsical vein the other day. He said: "I see these self-righteous mining journals are hopping on the poor cuss that sells a share of stock again. I once had a friend over in Utah; he had a good little mine, and he read in one of these righteous journals the advertisement of a man that manufactured a wonderful mill. It was four times as good as any other mill on the market. The advertisement in this righteous journal used these very words. So my friend went out and sold some stock to buy and erect one of these wonderful mills. When the mill was erected, it proved an absolute failure; and then this very righteous journal, which through its advertising columns had induced my friend to buy this fraudulent mill, turned right around and denounced him as a wild-eater, and a shyster for having sold stock to buy the mill. It appears like there is a lot of people terribly interested in protecting the dear public from the miner but nobody is interested in protecting the miner from the dear public."

I quote the above as an illustration of just one of the ten thousand ways of getting money fraudulently without the use of stock certificates.

Ball-Mill Practice

The Editor:

Sir—A perusal of Mr. Curtis Lindley's article on this subject leaves me unconvinced that the major portion of the crushing in a ball-mill is performed by transferred forces. Let us assume that a ball-mill has a capacity of 100 tons per 24 hours under ideal conditions, that we wish to crush that amount, but that through inexperience we do not maintain the correct pulp-density. If the feed be too 'thin', the passage of solid particles through the mill is too rapid; therefore the chances for any individual particle to be hit are lessened. I do not think Mr. Lindley's idea that crushing is adversely affected in a thin pulp owing to the outward-moving currents induced by the approach of two bodies is entirely correct, because the

contents of a revolving ball-mill are in a state of great confusion and there are many interfering currents. The mill-duty falls solely because the ore does not remain long enough in the mill. On the other hand, if the feed be too 'thick', the mill-duty is soon impaired by the coarseness of the discharge. Passage through the mill is slower, chances for any one particle to receive a blow are better, yet the crushing is not as fine as it ought to be. This is due to the cushioning effect of a thick pulp. Given two mills, one loaded with spherical steel balls, the other with quartz of like shape (I assume a quartz sphere for purpose of illustration only), we find that the former will handle a denser pulp and, of course, a larger tonnage. This makes clear that an important factor in crushing is the specific gravity of the crushing medium. Mr. Lindley does not think that more than 5% of the crushing is done by direct impact. I wonder whether he will find much support for this view. The assumption that the greater part of the crushing is done by transferred energy appears to be reasonable only in the case where a heavy ball falls on a number of small ones. When a ball falls on a stack of balls temporarily at rest with respect to one another, in a revolving mill, the energy not dissipated as heat is transmitted to all points of contact. It is easy to imagine the insignificant amount of energy at any but the highest points of contact. Many of us have heard of the old-time showman who permitted an iron ball which he placed on his head to be struck by a heavy hammer. It seems to me that the major portion of the crushing in a mill is done by the clashing of moving balls, whether the movement be roughly perpendicular or lateral.

PAUL T. BRITEL.

Thomson, Georgia, February 19.

The Status of Gold

The Editor:

Sir—I have followed the discussions of the gold and money problems in your paper with great interest, and it appears to me that certain usages in England with regard to currency and coinage have not been referred to in these discussions, and perhaps they are not properly understood in America.

In Britain, any person having a certain quantity of gold, is entitled to send it to the Mint, where it will be assayed and coined, and the same amount of pure gold will be returned to him in coins of standard fineness, without any charge whatever, the Government bearing all wastage and other losses. Gold is therefore coined at a loss to the Government. On the other hand, silver and copper are also coined, at a profit that more than covers the loss in the coining of gold. Furthermore, the British Government has not set any value on these gold coins. It has called a certain weight of gold of standard fineness, a 'sovereign', and has said that 20 shillings is equivalent to a sovereign, but that more than 40 shillings is not legal tender in settling a debt.

Many have suggested that the respective governments should raise the price of gold, from approximately 85

shillings per ounce of pure gold, in England, and 20.67 dollars in the United States, to a higher figure, apparently forgetting, or not realizing, that shillings and dollars are only the equivalents of a certain weight of gold. They have not realized that coined gold is simply a commodity, that is, subject to the laws of supply and demand, like any other commodity. They have probably been misled through the practice in England, of selling most of the gold to the Bank of England, which gives in return sovereigns or bank-notes equivalent to about 85 shillings per ounce of pure gold, exacting only a very small commission, thus saving the customer the delay in connection with the coining of his gold. That the British authorities are well aware of these facts is shown by their having made an arrangement with the principal gold producers to sell all their gold output during the War through the Bank of England at the rate of 85 shillings per ounce for patriotic reasons.

At the present time, bar gold is sold in England at 120 to 130 shillings per ounce. There is a general opinion that this rise in the market value of gold is the direct result of the fall of sterling exchange. From this opinion I venture to dissent. The rise in the market price of gold is the direct result of the demand for gold, probably encouraged by the British government.

To understand what the rise in the market value of gold means to Britain, it may be well to follow in a simple way what happens when a British producer sells his gold. It is produced in a British possession by British capital and costs for its production, say, £4.25 per ounce. It is sold or exchanged in England, in the best market, and for this gold the producer now demands between £6 and £6.5 per ounce, either in gold sovereigns, or their equivalent in other goods. The British public must have gold, and to get it they must now give at least 6 sovereigns for the same weight of gold for which they previously gave 4½ sovereigns. It certainly does appear at first sight to be somewhat paradoxical, to buy 4½ sovereigns with 6 sovereigns, but when it is considered that as soon as the transaction is completed, the 4½ sovereigns at once becomes of the value of 6 sovereigns, the anomaly disappears. Not only that, for the market value of all the nation's stock of gold is raised from 4½ to the new standard of 6. The appreciation in the value of the sovereign will only be limited by the demand for gold and there is no saying where it may stop. This rise in the value of gold costs the British nation nothing, for the increase is merely paid by one member of the family to another member, and at the worst it is only robbing an English Peter to pay an English Paul.

British capital controls over 60% of the gold output of the world. According to Mr. Lindgren, the whole of the United States production is used for industrial purposes. As soon as the United States producers can be made to understand that their government must have gold, with the example of Britain before them, they will insist on being paid a higher price for it. If the United States must buy gold from external sources, it will probably have to pay the British price for it, and we may

therefore confidently expect that the price of gold in America will approximate to the price in Britain. Thus means a great deal to Britain, for its debt to the United States was contracted on a basis of 85 shillings or \$20.67 per ounce of gold. If the price of gold in the United States becomes 130 shillings, for instance, Britain's debt of, say, eight and a half billion dollars would be at once reduced to about five and a half billions, and if Britain can force the price still higher, which she may be in a position to do, she will benefit to a still greater degree, at the expense of every other nation.

There are other inducements for Britain to attempt to raise the value of gold throughout the world. Its labor costs are much higher than previously, but as they cannot now be very far from the zenith they will probably not be much affected by an appreciation in the value of gold. On the other hand, if the United States must import gold at a higher price, its labor costs will probably continue to rise for a long time. In any case, America is much handicapped by long haulage and high freight-rates, and if the latter are raised, wages generally must be raised also. If labor costs in America continue to rise, Britain will once more be placed in its former advantageous position, as regards its ability to export its manufactures at a profitable rate, and so may regain, in course of time, its proud position as financier of the world.

Toronto, February 20.

Patents and Progress

The Editor:

Sir—With much of Mr. Greenawalt's recent article on this subject I am in hearty accord. Nevertheless, as there are some phases of patent law where Mr. Greenawalt's views seem inadequate, a few remarks covering these omissions may be pertinent.

If Mr. Greenawalt had used the terms 'Socialism' and 'Bolshevism' more concisely his meaning would have been clearer. Politically, 'Socialism' may be defined as the public ownership of all means of production, and 'Bolshevism' as socialism put in practice on a communistic basis. But much of what Mr. Greenawalt calls socialism—such as a doctor devoting his life without pecuniary reward to find a cure for tuberculosis—is not political socialism at all, but that unselfish co-operation of individuals for social purposes which has raised mankind from savagery to civilization. On my first visit to Santo Domingo, I was startled by the lack of such public utilities as municipal water and sewer systems or rural wagon-roads and bridges. At the start I was unable to explain this defect in an apparently intelligent population occupying a fertile country, but it soon developed that the cause lay in the extreme selfishness of the people. As the citizens refused to contribute any time or money whatever for social purposes knowingly, all the public revenue had to be collected surreptitiously by custom dues and similar indirect taxation on consumption. Until, therefore, the Santo Domingans learn to modify

their savage individualism in favor of unselfish co-operation for social ends, they can never hope to pass from barbarism into civilization.

Granting that there is really no basic invention and that the best anyone can do is to cap and complete a structure of devices and ideas left by his predecessors, the problem becomes how to encourage inventors without injuring society. It is evident that Mr. Greenawalt's proposal to establish public laboratories, where would-be inventors may test their ideas, would be beneficial up to the point where it attracted attention as a source of political pork. The arbitrary period of 17 years for the life of an American patent is meant to protect the public from a possible undue mauling by the patentee. Sometimes this period is too short to enable the inventor to perfect his idea, as Mr. Greenawalt points out; sometimes it is long enough to create huge fortunes for various individual monopolists, among whom the inventor himself is rarely included. There seems no reason to oppose the extension of the life of a patent to that of its inventor, provided only that property in patents be modified in its nature.

And just here enters a practical condition of which Mr. Greenawalt has failed to take note, namely, the effect of a patent grant on existing industries. The grant that means a rich reward for its owner may imply appalling losses to many established trades. For instance, any invention that renders obsolete the previous devices for the same purpose will destroy the business of the makers of the latter unless they can obtain a license for its manufacture. Under present laws this is quite liable to happen, for the inventor can restrict his license to a single factory and that a new one. This is certainly unfair to established interests and quite unessential as a means for rewarding the inventor; in fact, it has often the opposite effect, for the established factories, driven to the wall, begin to 'infringe' the new patent, and then begins the long struggle of the inventor against the piratical litigation so well described by Mr. Greenawalt. In such cases, there seem only two alternatives for the poor inventor: either to be intimidated into selling his patent "for a nominal sum through a forced compromise", or else jump down the throat of some kind capitalistic whale, who, in return for legal defence, will want the lion's share of the proceeds.

Technically, a patent is a monopoly, despite Mr. Greenawalt's opinion to the contrary. A monopoly does not consist necessarily in the complete control of a certain commodity, so as to fix its price, but the exclusive possession of any means of producing the commodity that is not open to all on equal terms. Our present patent laws go even further than a mere grant for monopolizing the use and sale of one invention, because, according to the decision of the Supreme Court in the trial of the United States Shoe Machinery Co., a patentee is legally empowered to refuse to allow his devices to be used in connection with the inventions of others, or in the utilization of any unauthorized accessories.

Mr. Greenawalt remarks: "Manifestly, royalties or compensation that would be satisfactory to the inventor

would not meet the demands of a heavily capitalized company, and if a royalty charge is made to meet all conditions, the royalties must, necessarily, be large . . . If the royalties are excessive, no fault should be found with the inventor; and no fault should be found with the companies controlling the patents, for they are doing what other companies do under similar conditions." He may be right from the standpoint of those monopolistic manufacturers and their inventive protégés, who act on the motto 'the public be damned'. Nevertheless, the public is gradually finding itself economically in the United States and some day may refuse to be longer mulcted of excessive royalties simply for lack of equitable patent laws.

To sum up, there are seven weighty objections to our patent grants in their present form: (1) They grant a manufacturing and selling monopoly that is out of harmony with our competitive industrial system; (2) They may disturb, injure, and even ruin legitimate established trades; (3) They cause a vast amount of needless litigation; (4) They tend to benefit the capitalist at the expense of the inventor; (5) They fix no limit as to what the public must pay for the use of an invention; (6) They fix no penalty for failure to use an invention; (7) They enable the owner of one invention, as a prerequisite to its use, to prescribe the boycott on other inventions.

As a remedy for all these defects, many thinkers—such as the late Tom L. Johnson of Cleveland—have advocated the abolition of patents altogether. This might be good policy for a backward nation like Mexico, which has practically no native inventors and seems unlikely to develop any in the predicable future; but for progressive countries such a remedy would be worse than the disease. The lack of legal protection for their achievements would keep many persons from inventing, while the remainder would be forced to exploit their inventions in secret in order to profit by them. We would then have a recession to the medieval days of secret processes and of 'lost arts', because in ancient times a device could perish with its inventor.

Abolition being inadvisable, is a cure of the grave faults in our existing patent system feasible? I would reply affirmatively, provided the nature of the grants be altered. Instead of giving a patentee the right to monopolize his invention, let the grant merely recognize his right of property to the extent of permitting him to collect royalty from its exploiters. The New Zealand law, I understand, is based on this principle and allows anyone to make or use an invention on condition of paying a toll to the patentee. In case the latter is unreasonable in his demands, the rate of toll will be fixed by the courts. This may be what Mr. Greenawalt derides as 'Socialism', but in my humble opinion it is merely a rational application of that socialization which differentiates civilization from barbarism—the restraint of individual greed and caprice for the common good.

If we scrutinize the seven enumerated defects in the light of the proposed changes, we discover at once that both objections No. 1 and 2 disappear, for anyone can

then make and sell the new invention, while established trades can freely add it to their existing stock of goods. Thus much of the incentive to litigation would be eliminated, because the established interests, no longer threatened with loss by being excluded from making or selling the new device, would find it cheaper to pay the patentee his toll than to pirate his ideas at the risk of costly lawsuits. The need of little or no funds for legal battles would save the inventor from falling a prey to the grasping capitalist, while the public would be protected from the excessive royalties by the power of the courts to limit them. An invention, once patented, could be used legally by anyone, so nothing of value would be withheld from society; and, for the same reason, the power of one patentee to force a boycott on another's devices would be abolished.

On the new basis, it would be advisable to extend the duration of a patent to the death of its inventor. Such an extension could work no harm to the public, whereas it would stimulate invention by giving inventors both plenty of time to perfect their devices and to enjoy the reward after the perfection. If it be objected that no capitalist would subsidize an inventor when he could no longer obtain a monopoly, it suffices to say that he then could expect to obtain his reward as now from a share of the royalties. When the inventor's royalty came before the court for approval, the judge would always consider the cost incurred in developing the invention before giving his decision as to its reasonableness. While fewer patent lawyers would be opulent and fewer capitalists might enter the millionaire class under the new system, there would certainly ensue less risk of loss and surer rewards for the inventors, and, consequently, many more inventions of practical utility.

Whether our patent law is altered in principle or not, I support Mr. Greenawalt in his advocacy of a more scientific administration. Perhaps now that the Great War has convinced even a lawyer of the value of applied science in destruction, there may be a better chance for scientific men to receive some recognition in the law-courts and legislative halls for the constructive arts of peace. Up to date our patent trials have borne a close resemblance to those involving the mining rights under the Federal law of the apex, and both have often resulted in sad parodies of justice, and even of common sense, for lack of judges trained in technology.

R. B. BRINSMADE.

Ixmiquilpan, Mexico, December 30.

PRACTICALLY all tungsten ore now produced in the world is used in making tungsten metal or ferro-tungsten. Various salts of tungsten have been employed in the dye industries, but have been almost wholly replaced by cheaper chemicals. Over 95% of the tungsten production goes into the making of tungsten steel, which is in general use for high-speed cutting tools, permanent magnets, and saw blades. A small amount of nearly pure tungsten is consumed in making filaments for incandescent electric lights.

The Bunker Hill Enterprise—VI

Methods of Mining and Exploration: Fires Underground

By T. A. RICKARD

Skilful mining involves the adaptation of methods to conditions. In the course of the development of the Bunker Hill mine from a young prospect to a big mine, it has been found advisable, by those in charge, to make radical changes in the manner of winning the ore, that is, of breaking it and collecting it before removal to the surface. These changes have been rendered necessary, to some extent, by the increase in the width of the excavations made underground, this increase being due in part to the discovery of larger orebodies, but in part also to the change in economic conditions above-ground, notably in the mill and metal-market, whereby it has become advantageous to remove a larger width of lode-matter, that is, to extract material that by reason of better technical conditions has come within the economic limit of profitable exploitation.*

In the early days of the mine 'the ground was carried', or the wall-rock was sustained, by stulls and half-sets, supplemented by a small amount of filling, the timbers being loaded with waste so as to cushion them and prevent damage from falls of rock. When the stopes became larger, more particularly on the Bunker Hill side of Milo gulch, beginning in 1897, it became the custom to use full sets, together with an increased and better distributed proportion of filling. As is usual when employing this type of timbering, the back of the stope was kept nearly horizontal and there was no pronounced arching, so that the hanging wall, often extremely heavy, was supported entirely by timbers until the filling was placed against it. By the time this was done, at least two weeks had elapsed, the ground had begun to weigh so heavily upon the timbers as to crush them, and big slabs of rock had fallen from the hanging wall. See Fig. 1.

During this period the drift used for the removal of the ore was on the sill-floor, where it was subject to the pressure and squeezing of the mass of waste-rock settling down in the stope. Costly repairs were rendered continuously necessary in order to make room for the ore-cars and prevent obstruction to the tramming. Furthermore, the timbers and supplies needed in the stopes came down through raises on the foot-wall, which was a position most inconvenient for the distribution of materials over the large area occupied by the stopes. Several accidents occurred. They were not calamitous, but on top of other reasons, already stated, they were quite serious enough to call for a modification of this method of mining.

Here I may suggest that the 'square set' system of timbering, together with the scheme of stoping that it involved, was thought a wonderful innovation twenty or thirty years ago. The Western miner prided himself on it and introduced it in foreign districts, such as Broken Hill and Kalgoorlie. It was 'invented', or, more correctly, introduced, by Philip Deidesheimer[†] on the Comstock in 1860 and was heralded as a great improvement. During the last twenty years the use of the 'square set'

FIG. 1. FORMER SYSTEM OF MINING

without filling has gone out of fashion because it has been found a snare and a delusion. The idea it embodies is that of a carpenter rather than of a miner. The unrestricted use of it has led to big caving and the destructive collapse of mines in various parts of the world. No timbering by itself will support heavy ground; it will only delay a fall. To sustain rock it is necessary to use rock. Therefore all recent systems of mining involve the use of waste to fill stopes and the leaving of pillars of ground to sustain a heavy hanging wall.

*For the data used in this article I am indebted, as will readily be surmised, to Stanley A. Easton, the manager.

[†]He died in San Francisco in 1916.

In 1904 the method of mining in the Bunker Hill began to undergo change and in the course of two or three years it was developed into the system now in use, as shown in the plan and section in Fig. 2 and 3. The important features of this system are as follows:

1. A nearly vertical exposure of ore at the working face, instead of a horizontal or flat face as formerly. This permits the drilling of 'uppers' made by stoping-drills, instead of the slightly inclined 'water holes' of the old system. The broken ore falls toward the mouth of chutes placed on the foot-wall, and much of it passes by gravity direct into these chutes, diminishing the need for shoveling. Formerly the ore fell on platforms spread over the square sets, so that all of it had to be shoveled into a chute or into wheelbarrows. By the new method the ore falls continuously toward the chutes.

2. The ground is excavated in the form of a sharp arch, the crest of which is the intersection of the face of ore with the plane of the hanging wall. This utilizes the full strength of both ore and wall for maintaining the stope-cavity. Waste is introduced at the crest of the arch and distributed laterally over the stope by hand-tramming in small dump-cars running on a temporary track. The waste, so introduced, passes by gravity to any place where filling is needed, without further handling. In order to hasten the settling of the waste, it is usually wetted, by a spray or other means. When drained, it consolidates almost like concrete; all voids are filled immediately, particularly those against the hanging. Not only does this filling, thus carefully distributed, serve to support the hanging wall, but it excludes the air and checks any tendency of the hanging wall to crumble or break. Timbers needed in the stopes are handled in the same way as the waste, that is, they are trammed along the crest of the stope, and brought to their place of use with the minimum of labor.

3. Permanent haulage-ways are extended along the main level, at the foot of the stope, for disposal of the ore. Bottom-dump cars of special design and of 1½ tons capacity are used in harness with storage-battery locomotives. This foot-wall drift or permanent haulage-way is connected with the chutes in the stope proper by means of rock chutes (that is, chutes excavated in the rock) provided with steel lips for facilitating discharge. These rock chutes serve not only as a channel for moving ore from the stope to the cars, but they also furnish valuable space for storage. A temporary track is laid on the sill-floor of the stope, and, for the first few floors, it serves for the removal of the ore as it is mined, but after a short while, owing to the weight of the stope and the accompanying squeezing and crushing of the timbers, this temporary track is abandoned. All haulage henceforth is done through the main foot-wall drift, which is effectively protected against all stope-settling by the foot-wall rock in which it is run.

4. In this system of stoping, the cutting out of the sill-floor along the hanging wall is always done first. As the

sets go into place against the hanging wall and as they are extended upward, the advance is made toward the foot-wall. When that is reached, the hanging-wall sets may be five or six high. This is the critical stage of the operation, because no filling has been introduced as yet and no raises have been made for handling the waste. Once this stage is passed, all is safe.

Mr. Easton tells me this system of mining was developed and put into successful practice by William McDougall, the mine superintendent. No ground is now excavated by the old style of flat-backed stopes; any narrow veins, not requiring square sets, are mined with stulls and filling, but such veins have only been exploited below the No. 10 level.

In the Sullivan workings, which are in the Revett formation, the quartzite is dense, hard, and tough, but in the main workings, owing to the general fissuring both prior and subsequent to ore deposition, the ground is relatively soft. Near the main fault-fissure, it is extremely 'heavy'. No amount of timbering can hold the ground for long. Immediate and complete filling of the stopes is necessary to sustain the 'back'. The sets of timber merely provide temporary protection for the miners and a position from which work can proceed; the timbers cannot be expected to keep the excavations open permanently, and in most of the workings no unfilled spaces wider than two sets are to be seen. Usually the working-face has a space only one set wide. The chief care and the biggest expense are incurred in obtaining and distributing the waste for filling; the bosses underground give this phase of the operation their close attention. For this reason, and also to maintain a satisfactory grade of mill-feed from relatively low-grade stopes, it becomes necessary to sort the ore into wheelbarrows while the larger fragments of waste are thrown into the 'waste-corral' formed by 'lacing' slabs from the saw-mill around the square sets that are to be filled. This keeps the waste where it belongs—in the stope, not the mill-bin. No waste whatever comes out of the mine; any that may be needed for filling, over and above that coming from sorting and exploratory workings, is furnished through special raises in one of the convenient upper levels. These raises are run to tap fault-fissures known to be in soft ground; they are not used for exploration. The raise caves, and the waste from it is drawn over the chute-lip at the bottom into cars, thereby reducing the handling of such material as much as possible. Careful plans are made for the transfer of it into the stopes requiring to be filled. These raises are underground quarries; they have furnished many hundred thousand tons of filling at a cost of about 5c. per ton delivered into the stopes, and no injurious consequences have resulted or even been threatened by the caving. It is practicable to 'pull on' some of them for years; the broken rock continues to come, with the aid, once in a while, of a stick of dynamite to blast a block, or 'choke', and encourage a fresh movement. Formerly it was customary to run waste-raises into the hanging wall of the stopes themselves, but the hanging, when penetrated, was often found to be hard rock; indeed, if it was

¹These drawings were prepared for me by Harold M. Childs (U. C. '02), the company's chief engineer.

FIG. 2. CROSS-SECTION, SHOWING PRESENT SYSTEM OF MINING

FIG. 3. PLAN, SHOWING PRESENT SYSTEM OF MINING

not hard, the raise could not be maintained. The cost of drilling and blasting in such ground was excessive and the work sometimes seriously weakened the back of the stope itself. Such raises were likely also to tap fresh sources of water seepage, which became a nuisance and a menace. This method has now been entirely discarded in favor of the caving system already described. At one time serious thought was given to a scheme for using the empty returning ore-trains from the mill for the purpose of hauling the mill-tailing, to be dumped into the stopes below the adit. This method, besides its cost, would have the disadvantage of rendering the tailing unavailable for re-treatment at a later date. It could not compare in cheapness and efficacy with the present system.

Fig. 4 illustrates the timbering of a raise and chutes in the Tyler workings. Two chutes with a skip-way and a man-way are shown. This method has been abandoned. The objection to it is that the weight of material in the chute bursts the lagging and presses against the skip-way and man-way. Chutes and skip-ways should be kept entirely separate. I give Fig. 4 as a warning.

Fig. 5 shows the timbering of a station at a two-compartment inclined shaft in plan and section. This is the method of timbering still in use throughout the *Coeur d'Alene*.

Fig. 6 is the section of a stope supported by stulls, as still used. It is a standard method and shows a cribbed chute with a lip, together with a collar or platform for receiving broken ore and waste-filling, to be banked against the hanging wall.

Fig. 7 is a timbered structure that was used in driving the Kellogg adit, in order to expedite the tramming. It was protected by steel plates along its inclined surface and was pushed against the pile of broken rock in the face. A small scraper was pulled up the incline by a compressed-air hoist and dumped into the cars. The entire structure was moved on wheels, as shown.

Returning to the present system of mining, I venture to add further details. The chutes in the stopes are built in log-house style, with sticks of cribbing $3\frac{1}{2}$ ft. long, made from 6-inch round timbers of Douglas fir. These sticks, for purposes of economy, are generally split by a saw, and, to protect them from wear, are lined on the bottom with 3-inch fir or tamarack plank of random widths. Two-thirds up the sides they are spiked in place against the flat face of the split cribbing. The man-ways are built of full round cribbing, 6 in. diam., without any lining. This round cribbing affords footing for the passage of men and attachment for air-pipes. Where the inclination is more than 50°, ladders are spiked into place. The construction of chutes and man-ways is the same in square-set stopes as in stull-stopings. Chutes are spaced in accordance with the width or quantity of ore; the minimum distance between chutes being 25 ft., whereas the man-ways are placed 100 ft. apart. Where ore is plentiful the chutes are placed 15 ft. apart and the man-ways at intervals of 50 ft. only.

The development of a mine is based upon the physical structure of the orebodies and of the country-rock en-

closing them. The main fissure traversing the Bunker Hill property used to be known as the Wardner foot-wall, but now it is recognized as the Cate fault. For many years the fissure was considered the lower limit of the lode, because all the known orebodies were in the quartzite of the hanging wall. Therefore exploratory development work was planned on this supposition. When proved wrong, the method of exploration had to be changed. Between 1900 and 1902, a great deal of driving and cross-cutting was done on the level of the Kellogg adit without finding any important orebody. In the summer of 1903 new orebodies were found, and since then there has been no looking backward.

Here I may state that in the course of the development work done during the last 12 years, it has become evident that in depth the Bunker Hill ore-shoot is drawing away from the Cate fault. The stopes on the No. 10 and No. 11 levels were closest to it. The fault formed the hanging wall of these stopes, and this was partly true of the No. 12 level, where much ore was stoped from between the hanging wall and the fault. On the lower levels only the east end of the Miller stope on No. 13 level touched the fault, for a distance of 150 ft. out of a total stope-length of 850 ft. The Day stope, on No. 13 level, is not closer at any point to the Cate fault than 300 ft.; the Plennons stope, above No. 14 level, comes no nearer than 200 ft.; and the Newman stope, on No. 15 level, no nearer than 400 ft. This structural relationship between the main ore-shoot and the principal fault has influenced, in large measure, the method of mining. In places the fine-grained galena near the foot-wall looks like graphite. Some of the miners had the old-fashioned idea that, being so fine grained, it must be rich in silver; so they took some of it away with them in their dinner-buckets, until they were disillusioned. In an accompanying illustration, the reader will note a beautiful example of normal faulting as seen in the Mike stope on the Frances vein in January of this year. The photograph fails to make clear the one foot of solid galena directly underneath the white vein of quartz, but the line of the fault-selva and the 'drag' are fairly well shown.

At the beginning of 1903 a new plan of exploration was started, namely, that of tracing the known ore on the Reed tunnel-level by means of short cross-cuts on successive lower levels, so that, step by step, its extension on the dip was traced. Soon it was ascertained that the main orebodies had departed from the line of projection previously assumed and also from their supposed relationship to the so-called Wardner foot-wall. This prime fact being once established, the ore was readily uncovered on the No. 7 and No. 8 levels, which are 400 ft. and 200 ft. respectively above the Kellogg adit. The extremely productive Cary and July stopes were opened up in 1904; and on St. Patrick's day in the same year the great March orebody was cut on the Kellogg level by a cross-cut 200 ft. from the line of the adit itself, but in a more easterly position than had been surmised. Within five years the production of the mine was more than doubled in tonnage and the grade was 75% higher than previously. During

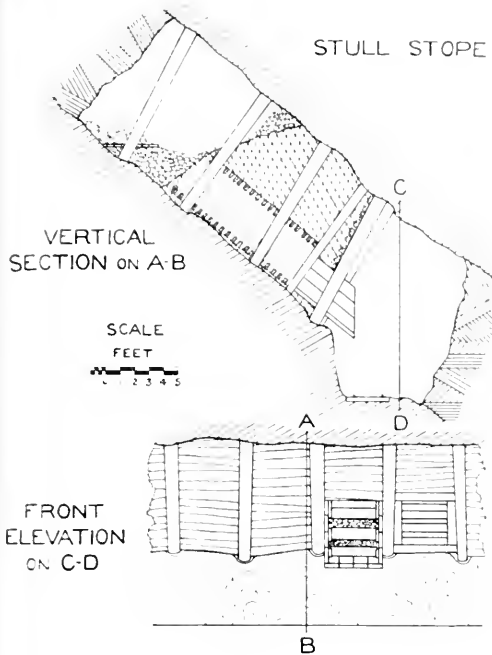

Fig. 6

Fig. 5

FIG. 7. STRUCTURE FOR EXPEDITING REMOVAL OF ROCK IN THE KELLOGG ADIT

1905 the sinking of the main shaft was begun and in 1906 the ore was cut on the 10th and 11th levels, which are 200 ft. and 400 ft. respectively below the adit. On the 11th level the Cameron ore-body, which extended directly under the Gate fault, was over 800 ft. long and was stoped on the sill-floor for a width of 180 ft. This stope is still productive and the eastern end of the ore has not yet been determined; it has made a yield already of 905,000 tons, which is at the rate of 8013 tons per vertical foot. This main Bunker Hill ore-shoot has been continuous from grass-roots. In addition, numerous other large and high-grade stopes are now being worked, so that 47.6% of the mine output has come from ore-shoots* other than the one on which the discovery was made in 1885. Outside

grand total of \$22,000,000, over \$20,000,000 has been paid since 1904.

Experience in the mining of lead deposits elsewhere shows that in depth they usually become contaminated with an increasing proportion of zinc-blende and pyrite together with other undesirable minerals, the presence of which comotes an impoverishment in lead and silver. In this mine, however, no such unfavorable change is to be noted. The deepest level, which is No. 15 and is 1200 ft. below the Kellogg adit, or 3000 ft. vertically beneath the surface, shows ore of a grade and composition superior to any heretofore mined on the upper levels. To the remarkable uniformity in the character of the ore, the mine owes its great and profitable production. This is attributed by geologists to the fact that the workings of the mine have not passed through the altered sedimentary beds that enclose the lode-channel from grass-roots downward, because the lode is inclined at a low angle to these beds, so that whereas physically the mine has attained great depth it is still high in the stratification. The wonderful network of fractures continues, and with it the conditions that were favorable to chemical interchanges between mineralizing solutions and the shattered quartzite. When the ground becomes 'tight', as a miner says, and the fractures become fewer in number, then it may be anticipated that the lode-channel will exhibit impoverishment. Of that there is no sign as yet.

In the past, as in most large mines, fires underground have been a cause of much annoyance and expense, but, fortunately, only one life has been lost from this cause in the whole history of the Bunker Hill. These fires have originated in the stope-timbers, for the ore does not contain enough sulphur to ignite or burn. The most serious fire was in February 1906. A choked chute was blasted by a timber-man; either the charge failed to explode and merely burned, or the splintered wood was set aflame by the explosive; in some way the fire passed to the timbering, extended up the chute, and was soon rampant in the dry timbers of the Flint stope above the No. 7 level. At that time, 13 years ago, little or no fire-fighting equipment was available and the oxygen-helmet was unknown. However, every available appliance was put to good use. By plentiful employment of brattice-cloths and ventilating-pipes, an approach was made to the fire and the first attempt was started to extinguish it directly. Some good work was accomplished, but it was soon ascertained that the fire had passed beyond reach into sets within the body of the stope; whereupon it was attacked from the No. 6 level, 200 ft. overhead. So-called water-drifts were run by miners working on 6-hour shifts. These drifts were on a dead level or slightly down-hill and were made as small as sufficed for a working space, that is, 4 by 5 ft.

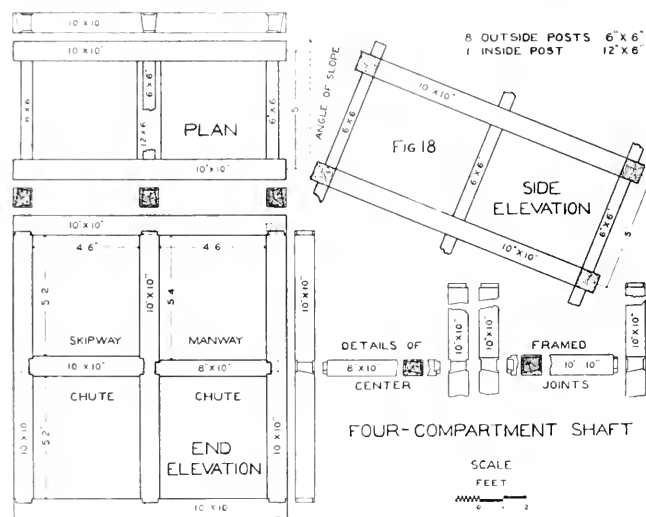

FIG. 4

these larger orebodies, there are numerous stopes on the quartzose veins that extend from the main lode, which, as the reader will recall, is characterized by a gangue of siderite. These quartzose orebodies have been stoped individually for distances of over 1200 ft., for widths ranging from one foot to 15 ft. A few of the wider veins are mined by square sets and filling, but most of them are mined by means of stulls and cribbed chutes, as described in the earlier part of this article. These quartzose veins appear to be older than the Bunker Hill orebody, as indicated by their relation to the faults. It is remarkable, having regard to the old notion of the Wardner foot-wall, that these veins occur exclusively below that fissure, which on the upper levels seemed to be the lower limit of the lode.

How these discoveries and the better method of mining contributed to the prosperity of the Bunker Hill enterprise is shown by the record of dividends, for out of the

*Up to January 1, 1919, the mine had produced 8,275,913 tons of ore; 52.4% of this had come from the main, or Bunker Hill, ore-shoot.

NORMAL FAULT ON THE FRANCES VEIN

MILO GULCH AND THE SULLIVAN WORKINGS

THE OLD BLUEBIRD CABIN AND THE PHIL SHERIDAN OUTCRO

The first of these drifts was run in the form of a crescent so as to encircle the entire area on fire. As soon as the surveys showed that this had been completed, this encircling drift was pumped full of water. The stream percolating from it formed an effective curtain of water, which restricted the fire within a small area. Then other water-drifts were run, so as to form a gridiron of openings above the burning area, and as fast as each drift was completed it was pumped full and kept full of water. That these methods were effective was shown by the scalding water that emerged on the No. 7 level, below the fire. Efforts also were made to reach it from below by ascending man-ways and carrying pipes with water under pressure from pumps operated by compressed air. Red-hot rock was reached, but only limited results ensued. Meanwhile the running of the water-drifts was being pushed diligently and the descending shower of water increased until by the middle of July—five months after the start of the fire—the entire area was under shower and the fire at length was extinguished. All this was done without loss of life or injury to anyone, although at times the workings adjacent to the fire were full of carbonic acid gas, which had the effect of rendering several men temporarily insensible.

In October 1912 another fire broke out in a station at the head of the main shaft, but, thanks to a superior fire equipment, including oxygen-helmets and trained men, this was extinguished in a few days. The station was not re-timbered; instead, it was lined with concrete distributed by means of a pneumatic gun. Much of this concrete was reinforced with steel bars. Later, it was decided that such reinforcement was unnecessary, the massive and well-arched concrete lining being sufficient to support the ground. Over 1000 cubic yards of concrete was used; the bins and approaches to the station, as well as the station itself, being lined with concrete from one to five feet thick. At this time also the station at the collar of No. 2 shaft was lined with concrete, and later certain parts of the adit, where soft and heavy ground required frequent re-timbering, were covered with concrete as a permanent protection.

With the exception of the thick and highly silicified beds of the Revett formation, which are slow drilling and tough breaking, the ground, both in the lode itself and in the outer country, is easily drilled and breaks well. A round of holes in a drift will break $4\frac{1}{2}$ ft. and is readily drilled in less than the 8-hour shift.

The ground breaks as well in cross-cuts as in drifts. To indicate the character of the rock, it may be noted that, including all development and shaft-sinking, only slightly more than half a pound of 35% gelatine, that is, the lowest desirable explosive procurable, is spent per ton of ore, as compared with more than two pounds per ton at Treadwell, for example, or $1\frac{1}{2}$ pounds on the Rand. For years the standard practice has been to perform all the mining on the day-shift, leaving a small crew at night to clear the broken ore and rock from the drifts and cross-cuts, to do the tramming, and to attend to the minor jobs incidental thereto. This practice is made possible by the

large amount of ore opened up, the exceptional storage afforded by numerous capacious chutes and spreading of operations over an area that includes 19 different stopes, some of which singly can provide over 300 tons of ore per shift. The advantages of confining the drilling and blasting to the day-shift are obvious; day-work is pleasing to the men; moreover, it facilitates competent supervision, for each workman and each boss has his own sphere of operations for which he is directly responsible, and he has a place where he is able to plan and perform his work without clashing with the ideas or doings of others. This free scope appeals to the intelligent man. Sunday work is avoided as much as possible. Those who desire to work on the seventh day are given the opportunity to do so, but except during the War, when there was a shortage of labor, it has been the policy of the manager to discontinue Sunday work. There was opposition to this custom when it was first established, so it was introduced by degrees, first by 'laying off' on one Sunday in each month, then two Sundays, until the men learned to appreciate that it was to their benefit. They came to like the custom so much that if ordered to work on a Sunday they would demur or find an excuse for 'laying off'. It is undoubtedly a fact that this recognition of a day of rest has resulted in better conditions from the standpoint both of the employer and of the employee, enabling the staff and the workmen alike to find time for the necessary change and recreation. The smaller number of accidents, both the slight ones and the fatal, while largely due to the safety-first propaganda and to prohibition, is to be credited also in part to day-work, with its attendant closer supervision, intimate knowledge of the workmen concerning any change of conditions in their place of work, and also to the opportunity for the healthful variation afforded by the spell of rest on Sundays.

Nevertheless the mine is productive even on Sundays, because the train-crews remain on duty and haul ore from storage in the numerous chutes underground, so that the operation of the concentrators and smelter is continuous. The manager always keeps in mind the fact that the mine is the mainspring of all the resultant activities, and the work of the entire enterprise is based upon that fact.

All materials are carried through the raises connecting with the backs of stopes. Dressed steel, however, and tools in general are carried down the man-ways by 'nippers', or young boys, to the tool-car on the level below. Water for drinking is piped to all the levels from the surface; from stations on the levels it is carried to the stopes by hand in 10-gal. galvanized-iron cans furnished with a hose. Small canvas water-bags are supplied to the miners at cost and many workmen use them to take their individual supply of water to their place of work. These water-bags have proved satisfactory. For sanitation, flush-closets are provided on most of the levels, at or near the shaft; they discharge into the drainage system of the mine and eventually into the sumps below the pumps. The dilution is said to be so great as to prevent any unpleasantness, there being a flow of water in the mine ample for flushing the latrines and preserving sanitary

conditions. The water from the mine is used in the mills; it amounts to 600 gallons per minute.

VENTILATION. The natural circulation of air in the mine is excellent throughout the workings above the adit, thanks to the numerous connecting workings, and for several levels below the adit as well; it is regulated by the difference between the temperature underground and that at surface. When the atmosphere outdoors is warmer than 56° F., the air in the mine flows outward, and when the thermometer registers below 56° F. on the surface the air flows inward through the adit. In a few stopes where men are working and in which square sets are used the temperature rises, after the third cut has been made, from 60° to as much as 80°. The air is humid and stimulates perspiration. The workings adjacent to the Cate fissure are particularly warm, owing probably to chemical action in the crushed rock. After a few years the filling in the stopes shows oxidation by its change of color and the cementing of the broken material. Heat is due to this cause and to the decay of timbers. In the stull stopes the air is cooler than in the square-set stopes. On No. 10 level (200 ft. below the adit) the humidity reaches the dew-point. On the same level the natural ventilation has been supplemented by a blower of the Sirocco type, which delivers 60,000 cubic feet of air per minute as a down-cast. This fan is actuated by a 30-hp. motor. In addition, an exhaust-fan of the same type, and of 45,000 cu. ft. capacity, has been erected recently on the Kellogg level, close to the No. 2 shaft. This will serve to establish an up-cast, drawing the air of the warm stopes.

The timber used in the mine comes from the north fork of the Coeur d'Alene river and from the lake of the same name; it is brought by train and delivered at a cost of 6½ to 7 cents per linear foot of 10-in. round poles.

The chief question regarding a mine is its health as it grows old, for upon that depends its economic life. On the 1500-ft. level, which is 1200 ft. below the adit and 3000 ft. beneath the nearest surface, the lode is reached by a cross-cut 800 ft. long, from which a drift extends for 400 ft. each way in the Bunker Hill main ore-shoot. The level, for this 800 ft., is in ore for its full width. The cross-cut has been extended to the No. 2 shaft, a distance of 600 ft., and cuts the Frances fissure, in which 6 ft. of ore shows, and also the Barr fissure, which likewise shows a full stoping-width of good-looking ore. All the veins look normal and yield ore of an average grade or better. In short, the bottom of the mine is healthy; the showing of ore is as good as at any level above; and the life of the enterprise has as yet no visible end, although, of course, the Bunker Hill lode, like all others, must become impoverished eventually as the mine is deepened. The workings have gone through the Revett quartzite and are now in the Burke formation. These are the terrains to which profitable mining in the Coeur d'Alene is largely confined. The Burke quartzite has a thickness of 1500 ft., this formation has been reached recently by the deepest workings; therefore stratigraphically the conditions continue favorable.

(To be continued)

Perhaps the most striking feature of Burma's export trade during the past five years has been the rapid increase in the exportation of minerals. The principal metals exported are wolfram, lead, silver, and tin. Wolfram and tin are found in the mountains separating the Tenasserim coast from Siam and in the northward extension of these mountains into the Southern Shan States. These metals are exported chiefly from Rangoon and from Tavoy and Mergui. Before the War most of the wolfram went to Germany; now it all goes to the United Kingdom. The tin ore is generally shipped to the Singapore market, to India, or to the United Kingdom. The wolfram and tin of Burma are produced by many companies, large and small, and mining methods are generally crude. All the lead and silver exported from Burma come from the Bawdwin mine. This mine is situated at Bawdwin in the Northern Shan States, and is operated by the Burma Mines, Ltd. The ore is refined at the smelter at Namtu near the mine, and the lead and silver are sent by rail to Rangoon. The lead is sent principally to Ceylon and India, where it is said to be used in the manufacture of tea chests; but a good proportion of this metal was sent to England, and, especially during 1917, to Vladivostok. The silver is exported as 'treasure', principally to India, where it is minted into rupees.

THE COMBINED OUTPUT of the coal mines in the Loire basin in 1918 is estimated at 4,918,116 metric tons, an increase of 380,276 tons as compared with the preceding year. The work of recuperation in connection with coke-ovens gave the mining companies a market for by-products hitherto imported. A great scarcity of fuel marked the beginning of the year 1918. Many factories had to close down for that reason. The shipment of considerable quantities of coal to Italy and the congested state of the railroad traffic also contributed to the crisis. The events at the seat of war called for an increased production, and the output of certain mines increased 15%. There was great rivalry among the mining companies, and secondary concessions hitherto abandoned were put into operation once more.

THE drinking water used by miners underground is of as much importance as that in use on the surface. The water used for drinking purposes underground should be free from filth or contamination. Many diseases are spread in this manner, among which are common colds, influenza, pneumonia, and syphilis. Where drinking water is piped underground a simple sanitary device may be arranged by means of a pipe, with a union on the end too big to be placed in the mouth. It is better so to place the union on the end of the pipe that the water will not come in an upright stream, but pour out on the side.

THE U. S. Geological Survey now has available for distribution its annual statement of the production, exports, and imports of sulphur and pyrite in the United States in 1918. The sulphur produced in the United States in that year was 1,353,525 tons.

The Human Element in Mine Operation

By EDWIN HIGGINS

INTRODUCTION. To operate at maximum efficiency a mine must have not only suitable equipment and proper methods; it must have laborers who return an honest day's work for the wages paid to them. Bearing in mind that in metal mining generally from 60 to 70% of the total cost of production is chargeable to labor, it may be seen readily how seriously labor performances may be reflected on the cost sheet.

THE HUMANE METHOD. "How can I get better co-operation from my men?" is a question often asked by mine officials. In the last two or three years, during which the efficiency of labor has decreased to such a great extent, this question has been frequently asked. The answer is to be found in the fact that the degree of loyalty in a workman is a direct measure of his value to his employer. The higher the degree of loyalty, the more valuable is the man. Therefore, in order to secure the best results, it is necessary that workmen be accorded such treatment as will win and secure their loyalty. To accomplish this there is no better method known than the policy of the square deal and humane treatment. The truth of this statement has been demonstrated by thousands of employers.

A striking example of employers of this class is James H. Foster, of Cleveland, Ohio, a man who converted a small shop into a steel-fabricating plant with a yearly business of \$25,000,000. The following paragraphs from an article recently written by Mr. Foster are of interest:

"Men are square. I believe that to the very underpinning of my soul. I do not mean some men, or even the average man. I mean the overwhelming majority; all but the few scattering votes that do not affect the final returns. I suppose that the men out in my plants are no different from men in Duluth or Birmingham, and that I have a right to judge by them. As I have worked with these men and played with them they have continually brought home to me the fact that the big thing a human being wants is a decent right to self-expression and self-respect. And he resents any attempt to deny him this right.

"The employer who takes men thoroughly into his confidence is making an investment with amazing possibilities. When we adopted the eight-hour day there was one department in which it seemed doubtful that we could get enough production to avoid a clear loss. I went over the situation thoroughly with the men in that department and explained the breakers we saw ahead. I have never seen a body of men take hold of a problem more intelligently and earnestly. Through their own efforts the production in that department became greater in the eight-hour day than it had been under the old ten-hour schedule.

"Any plan for increasing the contentment of workers must be built from the bottom. Our present personnel committees are merely an outgrowth of the old weekly conferences held in each department, when the workmen used to gather around the superintendent or the general manager and unburden themselves of all the knocks and boosts they had been storing up. Those old conferences give me mighty pleasant memories. I can still see the men sitting around on automobile frames, plumb full of intelligent interest, and talking out what they thought about things. If a demand was not reasonable the management seldom had to say so. The man's fellow workmen would "shush him down", and then, if necessary, take him into a corner later and argue the matter out. Then we grew so big that weekly meetings in each department were out of the question. So the personnel committee was born. The committee in each plant is made up of one representative for every thirty men, elected twice a year. The company's only stipulation is that he must be an American citizen and in our employ for one year. This committee lays all the problems of the men before the management. Its recommendations are always accepted, unless we are able to point out a clear impediment which the men had failed to take into account.

"I always tell our foremen that their work is divided into two parts: to know their jobs and to know their men, and that the second is the more important of the two. The foreman who gives the men under him a square deal, who leads them instead of driving them, is worth more to the company than a man who could write fourteen textbooks on his trade."

THE ROLE OF THE CHIEF. It is true that many dividend-paying mines are in charge of men who have little or no regard for the human element. It is equally true that many such mines are not operating at maximum efficiency, although they appear to be, because they are paying dividends. Where the ore is of low grade and every device must be used in order to squeeze out a profit, the successful operator will be the man who is surrounded by a crew of loyal workers. To illustrate this point, two extremes may be cited:

On the one hand, picture a manager who is a driver of men, getting results because his employees are afraid of him or afraid of losing their jobs. These employees have no kind thoughts for the boss; they refer to him in slighting terms and possibly make faces at him behind his back. On the other hand, let us consider a manager who, by humane treatment and the square deal, has won the respect and loyalty of his men. To sum up in a few words, his employees would "go to Hades" for the "old man". It is unnecessary to ask which of the above two managers stands the better chance of successfully operating a mine.

Labor may be divided into three classes: (1) The loyal worker; (2) the worker who lacks enthusiasm and is on the fence as regards responsibility to his employer; (3) the discontented worker, the trouble-maker. The problem before the employer is to bring as many of his men as possible into the first class.

The application of the principle of the square deal and humane treatment must of necessity originate with the manager, superintendent, or man in charge, whatever his title may be. For brevity he will be referred to herein as the Chief.

The development of loyalty and a spirit of co-operation within the organization should be one of the most important concerns of the Chief. If he has a natural disposition to treat fairly and humanely with his employees his task is not a complicated one. Lacking a natural bent in this direction it may not be a difficult matter to correct the fault.

Engineers as a class are analytical, and because faults can be found in almost any operation, they are likely to be critical, even hyper-critical. In searching for inefficiency or the cause of poor operating results, the Chief should first reverse the usual order of things and analyze himself. For instance he might ask himself, "How do I stand with the men? Are there any of them who would make a trip to Hades for me? How many of them would put a little extra effort in their work over and above what is called for by their day's pay?"

RELATIONS OF OFFICIALS AND BOSSES. It is not only important that officers and bosses be fitted for the positions they hold; they should be men who can and do work together as a harmonious unit. The spirit of co-operation should be strong, with every man doing his share to get results. It is unnecessary to point out the disastrous results which inevitably come when one or more men in an organization begin pulling in the wrong direction. Emphasis should be laid, however, on the necessity for securing co-operation.

The exact method of bringing about harmony and co-operation depends largely on the personality of the Chief. He may find it necessary, in order to remedy troublesome conditions, to shift his men about. He may have in his organization one or more men who are most efficient workers, but who are inclined to cause trouble. Ordinarily, it is worth considerable effort to change the viewpoint of such men, but if they cannot be converted, the organization is better off without them.

One of the commonest causes of discord and discontent is the disregard, on the part of the Chief, of that basic principle: responsibility and authority must lie together. No mistake can be made if this principle is followed throughout the organization. On the other hand, trouble is inevitable when it is ignored.

There is one simple remedy that may be regarded as almost a sure preventive, as well as a cure, for discord in the organization. Reference is made to regular meetings of officials and bosses. At such meetings operating troubles may be discussed and suggestions for betterment made; an opportunity is presented for the men to get

closer together and familiarize themselves with each others' difficulties and viewpoints. These meetings tend to develop those who have a natural desire to remain in the background and keep their ideas to themselves; they induce a greater interest in the work, and take away the idea of some that they are only cogs in a wheel. No one man knows everything, and six or a dozen heads, even though some of them developed only in the stern school of experience, are better than one head, no matter how refined may be the brain matter contained within it.

Meetings of this kind are being held by many mining and industrial companies throughout the country. Some of them are weekly, some semi-monthly, and some monthly. Many companies precede some or all of their meetings by dinners, followed by something to smoke and now and then some kind of entertainment.

TREATMENT OF THE WORKING CREW. The average man will without doubt respond to humane treatment and the square deal. In putting the policy into effect, it is important that as little noise as possible be made about things done for the men. Some companies are today nullifying the results of their work by shouting from the housetops regarding their philanthropy toward the working man. Procedure of this kind breeds resentment and can result in no good.

The aim of the management should be to remove reasonable cause for dissatisfaction, make such improvements as will tend to attract a high class of labor, and to so regulate relations with the men as to win their loyalty and respect. In working toward these ends it is essential that the Chief set the proper example by his attitude; and he must see to it that his officials and bosses reflect this attitude.

In looking for causes of dissatisfaction, or opportunities for betterment, attention should be directed to the following: Relations with the men, housing, feeding, sanitation, recreation and amusements, education, safety, social and religious affairs. The relative importance of the above factors depends largely on the class of labor, size of the operation, and location of the camp (isolated or otherwise). At small mines or smelters, it might be desirable and practicable to do only a part of the things indicated; at larger mines or smelters, there may be many other things that should be given consideration. Efforts of this nature are generally referred to as welfare work. This term appears to be rather ill chosen, for it is too suggestive of charity, a thing that working men do not want.

Humane treatment of men need not be accompanied by any lack of firmness on the part of the Chief or any slackening in the discipline of the organization. There need be no change in customary rules and regulations. Care should be always taken to see that men are fairly treated as regards payment for contracts and labor. Trouble-makers should be summarily discharged.

Neither does the policy advocated herein imply undue familiarity with the men, or a too apparent concern regarding their welfare. On the other hand, the Chief should not adopt with his men an air of aloofness; he should at all times be ready to exchange a civil word with

them. Loyalty can be secured by acts of kindness. By keeping in touch with home conditions and personal affairs of employees and lending a helping hand where it is needed, many a man can be won as a loyal friend. Acts of this nature, however, must be done without ostentation and should not be made to appear as charity.

An associate of Mr. Foster recently wrote: "Whenever we have a man killed, J. H. is badly broken up, and he isn't himself for a week. He will call me into his office and ask me all about the man's household; if the widow has plenty of money; if we have arranged with some department store to provide funeral clothing for the family; if the undertaker is making appropriate arrangements; if cars are provided for the funeral procession; if we are speeding up the operation of the State Workmen's Compensation law; if there is anything else in the world he can do. And then the next day he may call me in again to ask if I am sure things are all right."

Poor living quarters and beds infected with insects are frequently the cause of much dissatisfaction. The proper housing of men will do much toward attracting a permanent crew and keeping them contented.

Good food means good spirits, good health, and a sound body. Where the company runs a boarding-house, a study of dietetics is of importance. A table may be lavishly supplied with a menu so improperly balanced as to constitute a menace to the health of the men. This effects their ability to work, breeds dissatisfaction, and causes discontent.

Proper sanitation in and about the mine and camp has an important bearing on the welfare of the community. It plays an important part in keeping men in good health and in preventing epidemics. Cleanliness and tidiness should not only be encouraged about the home, but should be insisted upon in and about the mine. A campaign for better sanitation needs no outline, but should embrace attention to the supply of drinking-water, proper disposal of garbage, efforts to eliminate mosquitos and flies, cleaning of streets, attention to the change-house, removal of rubbish from underground, establishment of latrines, both underground and on surface, and similar details.

"All work and no play makes Jack a dull boy." This is true of miners as well as of other men. After all, men are only grown-up boys. They must have recreation and amusement if they are to lead a natural life. Every employee about a mine usually has a few spare hours outside those devoted to working, sleeping, and eating. If he is kept in the proper frame of mind during these spare hours, his spirit and capacity for work the next day will be the greater. Idle hours, aside from the depressing effect they have on the morale, invite opportunities for fomenting trouble. No argument seems necessary to establish these facts.

If the enterprise is a small one, the problem is difficult, because in this case the item of expense becomes important. The class and nationality of the workmen are important factors. Where the operations are on a large scale, probably the best start is a club-house, which may

embrace some or all of the following: a general assembly room (which may be used also for picture-shows or dances); pool and billiard tables, bowling-alleys, gymnasium, plunge and shower-baths. A counter for the sale of cigars and soft drinks may be added. Many club-houses are able to pay an attendant from the profit of such a counter. Bowling tournaments and boxing matches are popular. If there are a sufficient number of men interested, there is nothing better for promoting community spirit than a baseball team. An organization of this kind, however, must have possible opponents within reasonable reach. In camps where certain foreign nationalities predominate, it is well to provide one or two of their own games.

Where there are a number of children in the camp and no village school-house is within reach, an effort should be made to provide instruction, in both kindergarten and common-school grades. For certain bosses and special men, evening classes in rudimentary mathematics are sometimes of great value. Foreigners who speak only their native tongue may be made more valuable if given instruction in the English language. Educational work may be carried on to a certain extent through proper literature supplied in the club-house, also by the showing of educational moving-picture films. A valuable refinement is a free library.

Safety work is of great value from a humanitarian standpoint. It is a means of preventing much suffering, grief, and hardship, and lessening the number of widows and orphans. As a secondary consideration, experience has demonstrated that safety work promotes efficiency and also lessens costs. A further saving is to be made by accident-prevention work if the company pays its own compensation insurance. Even if the company carries its insurance with some outside concern, the prevention of accidents is of value. Practically every accident that happens in the mine, from a bruised finger to a fatality, costs something in loss of time and demoralization of work. In some parts of the United States, the men all walk out of the mine in case of a fatal accident and do not return until the dead man is buried. When a man is seriously injured, he requires the aid of others. His work stops and the work of those coming to his assistance stops. There is a further loss from the curiosity mongers who want to know what is going on and also from the man or men required to carry the injured man from the mine to the first-aid room.

Of almost equal importance to safety work is the ability to care properly for the injured. This feature can be taken care of by having a certain number of men trained in first-aid methods, and by providing proper hospital accommodations.

In camps that are sufficiently large, the holding of dances and various kinds of entertainments should be encouraged. Any activity of this nature that will tend to develop community spirit should be given support. Where practicable, it is worth while to go to some trouble to afford places of religious worship for members of the community.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

NEWS OF KINGMAN AND OTHER DISTRICTS.

HACKBERRY.—The Combination Silver Mines Co. has been formed by Los Angeles people to develop the old Combination mines north of Hackberry. This old property yielded silver in the early days of the Hackberry camp.

JEROME.—Six feet of cross-cutting has been done on the new vein opened 120 ft. north of the old vein of the Shea mine and samples run as high as 417 oz. silver and 14% copper. It is announced that sinking by the Verde Apex Copper Co. of the 280-ft. joint shaft of the Venture Hill and Verde Apex companies to the 500-ft. level, is to be continued without delay. Cross-cutting toward the Black Horse vein will be done at the 500-ft. level. A cyanide plant is being purchased for the Verde Inspiration mine. Sinking is being continued from the 530-ft. level to the 500-ft. level.

KINGMAN.—The main shaft of the Oatman Amalgamated mine west of the Goldroad has reached a depth of 530 ft. Sinking is to be continued to the 600-ft. level at which point exploration laterally will be started. Veinlets carrying appreciable amounts of gold have been encountered in the shaft. The head-frame of the 1 X 1 mine has been completed and the shaft is being sunk to the 300-ft. level. Messrs. Hill and Mattson, lessees of the Autler and Copper World properties, have shipped six cars of copper ore since November last. A winze is now being sunk to develop ore below the present level. It is reported that a foot of ore assaying \$130 per ton in gold and silver has been opened in the east drift of the Gold Ore mine. The west drift is in ore valued at \$130 per ton in silver and gold. This ore is being sacked and shipped.

PRESCOTT.—A road is being built into the Tip Top silver mine preparatory to bringing the new machinery recently purchased. Unwatering of the mine is under way. This property was worked for silver in the 'seventies.

COLORADO

NEWS OF THE STATE.—AN OIL-SHALE PLANT.

DENVER.—When one hears of the changes that are in progress in the various metal-mining districts of the State he is almost at a loss to decide whether mining is advancing or declining. For instance, the news that the Portland Gold Mining Co. has abandoned two of its large mills and that these plants have been sold to junk-dealers

tends to give one a pessimistic idea regarding the future of the Cripple Creek district. The 600-ton mill at the mine was abandoned at the time the 1500-ton Independence mill was completed about two years ago. The 800-ton plant at Colorado City has also been idle for some time. Before the abandonment of these mills much of their machinery was placed in the new mill at Victor. But, as an antidote to such news we learn that activities have been or are soon to be renewed in many other parts of the State and that mills that have lain idle for years are being overhauled for renewed service. For instance it is stated that the old Iron City mill at Black Hawk has been secured by a company that proposes to operate the Cyclops and Alaska groups, both former silver producers. Then, just over the ridge at Idaho Springs, we understand that the old Jackson mill is being refurbished for the concentration of ores from such mines as the Bride and Old Town. In this same district, W. E. Leebrick reports the successful promotion of a deal whereby the Mattie mine is to be again operated. If there is anything disheartening in the news regarding the junking of two big mills that formerly extracted gold and silver from Cripple Creek ores, we can find some measure of solace in the occasional discoveries, at greater depths, of substantial ore-shoots. These finds long since disproved the theories advanced by certain geologists, in the early years of the district, that the worth-while ore-shoots would be found only relatively close to the surface.

Mining men of Colorado see serious difficulty ahead if the surveyor-general's office is abolished as proposed in an omnibus bill recently presented in Congress. It is argued that prospectors will not bother with patent-surveys if all the business connected with them must be handled at the expense that will unavoidably be involved in having the office work performed at Washington. A little tempest of protest was inaugurated by the employees of the local surveyor-general's office and it has been boosted by well-meaning mining men until the subject has come up for serious objection by Congressmen from Colorado.

Aspen has credit for the development of at least one new strike—on the Libby Belle ground along the Park tunnel.

GRAND JUNCTION.—The Western Oil Shale Co. that owns valuable oil-shale land near the Colorado-Utah State line, has had erected by the Galloupe Shale Process Co. of Denver, a small but complete education plant, including engines, crusher, conveyor, retort of the Galloupe type,

condensers, bins, and buildings. The accompanying photo shows this plant as it neared completion.

During the past 60 days, this plant has been operated intermittently in test runs under varying conditions of feed, mechanical stirring, and temperature, with the object of securing reliable data relative to the capacity and efficiency of this kind of retort. Continuous runs have not been possible because the crusher is unable to keep up with the retort. The performance of the process has proved so satisfying that the Western Oil Shale Co. has placed a contract for increasing the capacity of the plant to 500 tons per day.

The single retort now in place has a daily capacity of 80 tons and makes an eduction of 95% of the available volatile hydrocarbons in the raw shale. Upon this basis the shale thus far treated has yielded an average of a little more than 50 gallons of crude or total oil per ton. The oil comes from the retort through 17 sets of condensing-pipes, each such set of pipes delivering a product having a specific gravity different from the other products. These fractions are not expected to be fixed nor sharply differentiated but they are sufficiently different to permit the immediate consumption of some of them without further refining. For instance the company's heavy auto-truck is operated upon lighter fractions just as they come from the retort.

In the proposed, enlarged plant, the handling of the shale after it is mined and delivered to the crusher will be mechanical. When the volatiles have been removed from the shale, the residue is dropped from the retort directly into an automatic stoker and all remaining fuel value in the rock is utilized in the fire-box. The thermal units in this spent shale will vary inversely with the thoroughness of the distillation of the shale. There will be found in every sort of oil-shale a point of highest efficiency in this eduction. The volatiles removed toward the close of the treatment possess relatively low market value and their removal from the rock is accomplished only by expending a quantity of heat much in excess of that required to remove the more valuable volatiles. Such residual substances are found most useful on the grates under the retort. The spent shale leaves the bottom of the retort at a cherry-red heat and so easily takes fire when supplied with air in the fire-box. If it were found that the hydrocarbons and the fixed carbon discarded with the shale would not furnish sufficient heat for operating the retort the deficiency would be readily adjusted by burning, in the furnace, some of the permanent gas that comes from the retort. In any event, the item of fuel is well taken care of under the Galloupe system. Some processes propose the burning of oil secured from their operations.

The mechanical engineer for the Western Oil Shale Co. has been tabulating figures for the cost of producing one barrel of crude oil. He gives the information that he believes the proposed 500-ton plant will manufacture such oil at from \$1 to \$1.25 per 42-gallon barrel. He hopes to have the plant operating upon a basis of 100 tons daily about July 1, 1920.

MICHIGAN

GOOD ORE FROM SENECA.—LABOR CONDITIONS.

Houghton.—Mass Consolidated has a million pounds of copper unsold at present. This it is said will not be sold at less than 20c. While the company has no plans for resumption of mining until the metal market improves it is interesting to know that more than 100 of its employees are continuing to occupy the company houses near the mine. Many of these keep their families in the company houses but are working at the Champion or Winona mines. Whenever the company may determine to re-open they will be the first to be re-employed at the Mass mine. The Mass company has sold for \$25,000, to the Sawyer-Goodman company, timber and surface rights on 600 acres, beyond the mineral horizon and five miles north of the mine shafts.

Mohawk made a remarkably good record for 1919, with costs at the mine approximately 9c. per pound of copper, exclusive of depreciation, transportation, taxes, Eastern office, and other expenses. Shafts now opened provide for five years of steady and continuous operation at the present rate. The expectation is reasonable that a copper content of 24 lb. will be maintained. All copper was sold at the first of the year. The company had \$2,000,000 quick assets on hand.

Hancock Consolidated has made its first shipment of 1700 tons of copper ore to the stamp-mill, since work was resumed. It is expected that this will net 14 lb. of copper per ton. Instructions were to send all of the material produced in development to surface, that could be milled at a profit. The shipment went to the Oseola Consolidated mill. None of the openings upon which the Hancock now is operating is in the Pewabic lode proper, but rather in a broken area east of the true Pewabic. Drifting now is under way on No. 12 amygdaloid. This was cut from a cross-cut from the 44th level. The general physical characteristics at this point are the same as those of No. 3 lode, which is the richest of any of those heretofore developed in this part of the mine. The underground working force is being maintained and efficient exploration operations are going forward at 12 different points, all of them indicating evidence of mineralization.

Seneca's third shipment of rock will be made soon. At the present time the physical development of the property is confined to shaft-sinking at No. 1. The lateral openings on the first level were completed to the boundary line some weeks ago. Those to the boundary lines on the second are now complete. The third level drifts have not been started as yet and will not be until the conereting in the shaft is completed. When that is done, which likely will take several weeks, the underground opening in the Kearsarge lode will progress with greater speed than hitherto has been possible. It will include laterals both north and south from the third level and will include the cross-cut to the lode at the fourth level.

The average return on the ore so far sent to the stamp-mill by the Seneca is 29.31 lb. The last shipment contained 35.73 lb. according to the final figures. This is a

remarkable showing, but in accord with the record expected as the mill return was 57 lb. The general run of the Kearsarge lode in the Ahmeek, Moltawk, Osceola, Wolverine, Allouez, and other properties is 25 lb. year in and year out.

At the Gratiot shaft, now being unwatered, the bailing has cleaned out the shaft to the seventh level and within a week it probably will be completely unwatered, for the work is progressing rapidly. It is a good many years since mining has been done at the Gratiot property and it is impossible to state the condition in which the shaft may be found, because it was abandoned with no expectation of resumption. The equipment at the Gratiot is in good condition on the surface now and everything is in readiness to start general underground sinking operations.

The third hole in the present diamond-drill develop-

MONTANA

MINING IN FERGUS COUNTY.

FERGUS COUNTY. Metal mining was relatively inactive in Fergus county, during 1919. The high cost of mining, a shortage of experienced labor, and the low price of base metals caused several mines to work at less than their usual capacity, and at some operations were discontinued entirely.

Two gold mines at Kendall in the North Moccasin mountains were regularly operated with profit. The North Moccasin mine of the Barnes-King Development Co. produced about \$10,000 per month. Two dividends were paid making a total of \$400,000 to date paid by this company. A new ore-body has been discovered and development work has disclosed a considerable tonnage of a good grade of ore. The Kendall mine was operated under lease by A. B. Fox and Lee Hilliard. The ore is

FIRST UNIT OF THE PLANT OF WESTERN OIL SHALE CO., NEAR GRAND JUNCTION

ment of the Calumet conglomerate lode now is being sunk, but at this particular point (this hole is the farthest north-east of all of the holes sunk by the Seneca) the stand-pipe is in a heavy rock. One hole has gone through 40 ft. of boulders at the present time.

There is no change in the labor situation in the Michigan copper region. No men now are leaving from the underground forces at any of the mines and there recently has been some increase to the forces of the Calumet & Hecla. The Mohawk and Copper Range mines have been giving a few men leave of absence. Indicative of the fact that these men appreciate the advantages that come from comfortable homes and good pay it is stated that they are returning to their native land to bring their families back to this country. There seems to be some difficulty in doing this unless they are naturalized citizens. Many of them are making the trip to personally conduct their families to this country. Some few are quitting and going back on account of their dislike for prohibition and its interference with their personal liberty, according to current reports about the mines.

low-grade but is all quarried from a big open-cut, making costs low. There is a large tonnage of ore yet to be mined.

The Spotted Horse and Maginness mines at Maiden in the Judith mountains produced a little ore. The Cumberland was entirely closed. Some tailings were re-treated at Giltedge without much profit. Development work was done at several prospects and it is expected that from now on there will be renewed activity in metal production in the county.

The coal strike caused several new coal mines to be opened and these are now supplying much of the local demand. The mines at Lehigh were closed by the strike but are operating at full capacity now. Their output is taken entirely by the Great Northern Railroad.

The sapphire mines at Yogo in the Little Belt mountains were operated again after being closed during most of the period of the War. The mines are owned by British capitalists, and supply most of the world's demand

There was great activity in searching for oil during

1919 in central Montana, especially in Musselshell and Fergus counties. The first well was brought in by the Van Duzen company and produced 600 barrels per day. The second well was brought in by the Roundup Oil & Gas Co. the middle of February. Both of these wells are in the Devil's basin about 25 miles from Roundup. The oil is a good grade of black oil. Many rigs are being hauled into the Devil's basin and adjoining fields and 100 test wells will probably be sunk in this vicinity during the coming summer.

BUTTE.—Every surface outcrop of silver and gold-bearing ore, as well as the dumps of the old silver mines, is being worked by numerous lessees, who sort and ship small lots of ore. With the price of manganese around a dollar a unit the manganese mining is rapidly recovering from the blow it received at the end of the War. A few small property holders abutting on Silver Bow creek are causing the mining companies, especially the East Butte and Butte & Superior companies, a good deal of trouble by lawsuits, based on the claim that tailing run into the creek damages their property.

GRANITE COUNTY.—The old silver mines in this district are reviving under the stimulus of the market for silver. The Scratch Awl mine is shipping high-grade ore to the smelter. The ore contains native and ruby silver and gray copper; the mine is owned principally by Butte men.

BEAVERHEAD COUNTY.—Old properties, including those at Bannock, Argento, Quartz Hill, and Glendale, which were rich producers in the silver days, are being reopened. At Argento, M. J. Scott and associates have found a good body of high-grade copper ore. This ore was opened in a drift on the 300-ft. level of the Jack Rabbit mine. It contains chalcocite or copper glance and assays 72% copper and 13 oz. silver per ton.

POWELL COUNTY.—The Emery Silver Mining Co., which owns the Emery mine, situated 10 miles east of Deer Lodge, reports that a contract has been signed and a deal closed whereby C. W. Galvin & Co. of 50 Broad street, New York, will sell 375,000 shares of the treasury stock to finance the development outlined for the Emery. The mill will be remodeled, electrified, and an oil-flotation unit of 300 tons per day will be added. The old waste-dump, which contains 123,000 tons of second-class silver-gold ore, will be milled, as also will be the fillings in the old stopes. The mine will be electrified, un-watered, and the parallel veins as well as cross-veins will be developed. There was only one ore-shoot developed in this mine by the former owners, who worked it until the Emery Silver company acquired the property, which consists of seven full and four fractional claims, as well as interests in adjoining claims. The Emery people came in possession of the mine in 1914 but met with a great many difficulties during the hard time of the War and were finally forced to suspend operations until additional capital could be secured. The test-mill of 50 tons capacity proved that with oil-flotation and electric power the property might be put on a paying basis.

NEVADA

RUSH IS STARTED TO RAND DISTRICT.—ACTIVITY AT EUREKA.

BENTON.—The Benton mining district, partly in Mono county, California, and partly in Nevada, is attracting the attention of Tonopah and Goldfield men, following the purchase of the Joe Main group of claims by the American Prospecting Club of Tonopah. There are a number of old mines in the district from which a large production of silver ore was made in the 'eighties and there is said to be an attractive field for prospectors.

LAFAYETTE.—The Lafayette, in the district of that name south of Candelaria, has been closed because of lack of funds caused by the refusal of the British Columbia bankers interested in the company to make further advances at the present rate of exchange. An effort will be made to re-finance the company in California.

GOLDFIELD.—The Red Hill will soon start drifting south on the 300-ft. level. For a long period all work except in leased territory has been done south of the shaft on the 500-ft. level, but, while promising shoots have been found frequently, an orebody has not been opened. Because of extremely heavy ground the work at 500 ft. has been slow and costly in recent months, but prospecting of this level will continue.

DIVIDE.—Ore 30 ft. wide and assaying \$40 per ton has been found in cross-cuts from a winze sunk a short distance from the 500-ft. level of the Gold Zone, south of the Tonopah Divide and on the strike of the main vein. The find was made practically on the line of the Tonopah Divide and Zone and the ore rakes south-east into the former. The orebody is the first of importance found in the Zone, in which a large amount of work has been done on the 500-ft. level. The ore is a sulphide containing tale.

RAND.—A rush of claim-stakers into the Rand district from Tonopah, has been started by developments in the Gold Pen, Nevada. Rand, and Mimms properties, particularly the first, in which new finds of rich gold ore are reported to have been made. Rand is 20 miles south-west of the old Rawhide district and it was discovered in 1907. The vein in the Gold Pen is from 25 to over 75 ft. wide, with rhyolite and andesite walls. The ore contains gold and silver and is free-milling. A 20-ton amalgamating plant is being built by the Gold Pen to treat ore blocked out which is estimated to be worth well over \$1,000,000, including 400 tons valued at over \$500 per ton. Small shipments of rich ore have been made. The Nevada Rand has produced \$50,000 in ore of medium grade and there is 40,000 tons of fair-grade ore blocked out. The Mimms has shipped \$20,000 in high-grade ore and there is said to be 5000 tons of from \$15 to \$20 material blocked out. The district has produced over \$250,000 in gold and silver.

ARROWHEAD.—Ore 3 ft. wide and assaying \$150 has been found in a drift driven west on the 100-ft. level of the Arrowhead, in which work has been resumed on the former scale.

MINA.—The main shaft of the Simon Silver-Lead mine is in high-grade sulphide ore at a depth of 470 ft. At the 400-ft. level it was supposed to be entering the foot-wall

ely on the 400-ft. level is over 150 ft.

wide. The engineering direction of the property is in the hands of Burch, Hershey & White, of San Francisco. Mr. Burch has been at the mine to direct development work and Mr. Hershey is said to be conducting the ore-tests. A 50-ton pilot mill, using oil-flotation, will be constructed at once. Blocked-out ore in the main deposit above the 400-ft. level is estimated at 500,000 tons. Drifts have exposed ore beyond the east and west faults. The east faulted orebody is high-grade carbonate for the width of the drift and a product assaying over \$100 per ton will be shipped to smelters.

LUNING.—High-grade silver ore has been shipped from properties east of Luning at intervals for many years.

the new superintendent, is in charge. He was employed formerly as superintendent of properties of the Cerro de Pasco Co. in Peru. H. P. Henderson, consulting engineer, has been at the mine. He says that as soon as the railroad spur is completed 2500 tons of coal will be shipped to the bins at the Locan shaft, which will then be unwatered. The shaft is 1200 ft. deep and water stands at the 985-ft. point. Shaft-equipment and pumps are as good as any in the West, Mr. Henderson said, including two 600-gal. station-pumps and two 600-gal. sinking-pumps. The flow on the 1200-ft. level when the mines closed was about 600 gal. per minute. A cross-cut on the 1200-ft. level had passed through the shale and into the ore-bearing limestone, beyond the Ruby Hill fault. The

THE MEADERVILLE SIDE OF ANACONDA HILL, AT BUTTE

although the district has been known of late years more for its output of copper. The Luning Consolidated Silver Mines Co. has acquired the groups of the Luning Gold Mines Co. and the R. B. Todd Mines Co. and has started work under direction of A. E. Lowe, manager of properties at Tonopah and Divide. A 4000-ft. tram will be laid to convey the ore from the mine to the flat road, and motor-trucks have been ordered to transport the product to Luning, whence it will be shipped by rail to Millers and treated in the cyanide mill of the Tonopah Mining Co. The reports give over 7000 tons of developed ore, assaying \$25, with a considerable quantity recoverable by sorting old dumps. L. F. Browne of San Francisco is president and manager.

EUREKA.—Rails and ties are arriving for the construction of 8000 ft. of track from the main line of the Eureka & Nevada railway to the mines on Ruby hill, held under option by the Ruby Hill Development Co. E. O. Holter of New York is head of this company. L. T. Herchmer,

Locan shaft is to be sunk to 1700 ft. to explore this area. The shaft has two compartments 4 ft. 9 in. by 6 ft. and another 6 by 8 ft. for ladders and pumps. A separate hoist and cages are used for the third compartment. The Eureka-Croesus has received two new compressors, the foundations for which have been prepared. A double-drum hoist is in transit to the property and will be placed at the Catlin shaft. Old workings of the Dunderberg mine are being cleared and the stopes contain much good mill ore. Julius Huebner, superintendent, reports two new discoveries of high-grade ore on the 400-ft. level, one 4-ft. face yielding a product assaying over \$200 per ton. The ore shipped to smelters is silicious and is not penalized for zinc, arsenic, or antimony. The Eureka-Holly has been installing larger hoisting machinery. The Eureka-Climax has an option on the Cloud claim and is driving its main adit to cut the orebody of the old Dead-broke mine.

VIRGINIA CITY.—At the Justice mine operated by

Donovan, Windish, and Robahn, a new shaft is being sunk to cut a large body of ore which was abandoned formerly on account of heavy ground. The operators expect to be taking out ore within the next few weeks. The Justice is one of the old producers of the Comstock Lode, and in the early 'seventies kept 12 mills busy.

Windish and Robahn, operating a lease on the Silver Hill mine, report that they have considerable ore blocked out on the 160-ft. level of the old shaft and are preparing to start the Donovan mill. Negotiations are reported to be under way for the purchase of the Dayton mine from the Hobart Estate Co. The Dayton is known to be a large low-grade property, and one reason for its being idle so long, seems to be the fact that its owners were unwilling to sell or lease the property at a reasonable figure.

Below Silver City the Yuba Construction Co. is completing the gold dredge for the Dayton Placer Recovery Co. Carloads of machinery and equipment are arriving daily, and before many weeks the gravel beds of Gold canyon that have not been worked since the early days of Virginia City will be yielding their gold to more modern methods than sluice-boxes and gold-pans.

UTAH

'UTAH COPPER' REPORT.—STRIKE CONDITIONS AT BINGHAM.

SALT LAKE CITY.—The Utah Copper Co. during the last quarter of 1918 produced 28,013,742 lb. of copper, bringing the total production for the year up to 110,591,608 lb., as compared with 197,978,557 lb. for 1918 and 206,174,442 lb. for 1917, which latter year holds the record for metal output of the company. The total quantity of ore milled during the quarter was 1,372,300 tons, being a decrease of 25,100 tons as compared with the third quarter. The average grade of the ore was 1.2439% and the average extraction was 81.56%, as compared with 1.1633% and 76.20%, respectively, for the third quarter. The higher copper content in the head and improved extraction are responsible for the increased recovery. The average net cost per pound of copper produced was 16.471c., as compared with 14.885c. for the third quarter. The value of the gold and silver in concentrate totaled \$249,787, and the miscellaneous income amounted to \$275,454. These two items combined are equal to 1.974c. per net pound of copper produced. The higher cost for the quarter was due to taking up of increased charges to cover State and county taxes, additional refining charges, and loss on retired property and equipment. The total net profit for the quarter was \$2,699,456, and after payment of a dividend of \$1.50 per share, totaling \$2,436,735, there was a surplus of \$262,721, as compared with a deficit of \$17,223 for the third quarter. The earnings for the fourth quarter are computed on the basis of 21.916c. per lb. for copper. During the period there was removed from the mine 801,433 cu. yd. of capping, making the total quantity of stripping handled during the year 2,062,911 cu. yd., as compared with 4,064,091 in 1918. The Bingham & Garfield Railway handled a daily tonnage of 19,026 during the fourth quarter, as compared with 9949 tons per day for the third quarter, 8734 tons

for the second quarter, and 13,520 for the first quarter of 1919.

BINGHAM.—The Board of Governors of the Bingham Commercial Club held a meeting on February 21, at which resolutions were adopted, vigorously denouncing the I. W. W.s for calling the present strike, and particularly the fact that they have no representatives, headquarters, or any authorized committee to represent the miners in settling their grievances with the operators. It was suggested at the meeting that a committee of disinterested persons be appointed to take up the matter of adjustment with the strikers and operators. On the same day, the strikers held a meeting, at which Albert Wills presided. He advised all miners to get out of camp and to remain away from Bingham and Park City, stating that, in this manner, recognition of the I. W. W. could be brought about. The strike is gradually fizzling out. Most of the mines report that at least 50% of their employees have returned to work. The Utah Apex Co. has again resumed milling operations. At the time the strike was called this property was producing about 600 tons of silver-lead ore per day. All told, it is estimated that about 600 miners have left camp, and no doubt some weeks will be required before the underground mines here will be back to normal capacity. The Utah Copper surface mine was not affected at any time by the strike order, and operations there are going along at normal rate.

OPHIR.—The Ophir Hill Consolidated Mining Co.'s output for 1919 was 33,895 tons of ore, from which was produced 373,435 oz. of silver, 6,595,743 lb. of lead, and 210,242 lb. of copper, with a gross value of \$705,856. The cost of extraction was \$262,737; of reduction, \$226,396, while transportation costs were \$61,089, making total expense of \$550,222. Therefore, the net proceeds for the year were \$155,634.

EUREKA.—Machinery and supplies have been ordered by the South Standard Mining Co. in preparation for active development. This property, consisting of 1200 acres, is situated in the eastern part of the district. A small amount of work has been done at the south end of the property, but the new three-compartment shaft will be sunk at the north end of the company's claims. A double-drum hoist, sufficient for a depth of 1200 to 1500 ft., will be installed.

Three feet of ore, which assays 27% lead and 12 oz. silver, has been encountered in the Eureka Mines property in a raise from the 1000-ft. level. This raise is being driven to intersect an ore-shoot opened some time ago by lessees in the Gemini property, which adjoins the Eureka Mines. It is said that one carload of ore mined by the lessees netted more than \$7000 and that \$27,000 worth of ore has been taken out by them since January 1.

The sinking of shaft No. 2 at the Chief Consolidated mine has reached a depth of 1100 ft. and concreting has been completed to a depth of 1000 ft., according to J. Fred Johnson, mine superintendent.

ALTA.—The Cardiff Mining Co. had an output of 6520 tons of ore during 1919, which yielded 102,043 oz. of sil-

ver. 3111 lb. of lead, 106,982 lb. of copper, and 952,917 lb. of zinc, the gross value of which was \$240,679. Expenses aggregated \$125,806, leaving net proceeds for the year of \$114,872.

Two fissures have already been cut in driving a cross-cut from the long tunnel at the Wasatch Mines property. The first fissure was cut some time ago and contained considerable good ore which could be shipped by sorting. This has been timbered and the cross-cut continued northerly to the Brain fissure, which it is expected will be reached in about 400 ft. The second fissure penetrated contained some good ore, but was narrow. The work that is being done in this part of the property has greatly reduced the water in the old Columbus Consolidated workings, and there is only about 30 ft. of water left to be drained before the old workings can be again explored. Since the cross-cut was started the water has dropped 20 feet.

BRITISH COLUMBIA

PROPOSED LEGISLATION BEFORE THE PROVINCIAL LEGISLATURE.

AINSWORTH.—A winze is to be sunk from the main cross-cut at the Cork-Province mine to cut the vein 200 ft. below. An electric plant will be installed to facilitate operations. The new work at the mine, which will cost about \$100,000, is being done under the supervision of R. H. Stewart. The 500-ft. cross-cut at the Index mine has passed through the No. 1 vein, and is being continued to cut No. 2. The mine is being operated by a Spokane company organized by E. J. Edwards. The cross-cut into the vein from No. 2 tunnel at the Kirby group has cut through 50 ft. of ore, and has not yet reached the foot-wall. Along the hanging wall was a 6-in. stringer of clean sulphide ore, which assayed from 60 to 2000 oz. in silver per ton and 60 to 70% lead. This stringer was not developed in the No. 1 tunnel, but an 18-in. stringer of equally rich ore was developed on the foot-wall, and the cross-cut is now pointed to cut this ore in the lower workings. About 12 ft. of ore in the centre of the vein is said to assay 22 oz. silver per ton. The high-grade ore is being sacked, and, it is said, pays for the development work. Stringers of similar ore have been cut in the Phillis and in the Gwennie groups, neighboring properties owned by R. D. Hearne and B. L. Eastman, respectively.

NELSON.—The Yankee Girl mine, near Ymir, has been examined by A. W. Newberry, of New York, who spent two weeks on the property, and took a large number of samples. This mine has been one of the largest producers in the district, some 400,000 tons of ore having been taken from the property. It was closed down in the early part of last year, as work was found unprofitable under the high cost of labor and supplies. The principal product of the mine is gold.

VICTORIA.—William Sloan, Minister of Mines, has introduced two bills in the Provincial legislature, now sitting. One, an amendment to the Mineral Survey and Development Act, provides that when a joint-stock com-

pany, other than a private company under the Companies Act, acquires an interest in, or title to, or engages in work on any mining property situated in a mineral survey district, it must forthwith notify the resident engineer of that district, and file with him full particulars thereof and a copy of the prospectus required by the Companies Act. The penalty for failing to comply with this provision is a fine not exceeding \$25 per day for each day that the default continues. The other bill is an amendment to the Mineral Act, and provides for the withdrawal from location and mining lands containing iron ore, which at the

ARROWHEAD MOUNTAIN, AND THE CAMP AT THE ARROWHEAD CONSOLIDATED SHAFT.

time of the notice in the 'Gazette' of such withdrawal are not included in any mineral claim or mining property held under this or any other act relating to mines and minerals. The amendment further provides for the disposal of iron ore contained on lands withdrawn by the Government under this section on such terms of royalty as may be later determined. The first amendment clearly is being introduced to prevent 'wild catting', and is a necessary precaution at the present time, when there is likely to be a considerable amount of company promoting in the north-west part of the Province. The second amendment has been introduced with a view to developing the iron and steel industry in the Province. In the past large areas have been held for speculation at absurd prices, and in several instances this has possibly prevented the investment of capital in steel enterprises.

STEWART.—A shipment of 250 tons of ore from the Premier mine recently was brought over the winter trail

to Stewart, where it was loaded on the G. T. P. steamer, 'Prince John', on the way to the smelter at Tacoma. R. K. Neill, one of the owners of the property, is reported as saying that a cyanide plant is likely to be built after development has advanced to such a point that a steady supply of ore is assured. Statements from those in a position to know indicate that the Premier is experiencing some difficulty through the activity of agitators among the workmen. Confidence is expressed, however, that this will not seriously interfere with the plans in mind for development and operation.

Preparations are in hand for the commencement of work on the Spider group, which consists of three claims lying north of Long lake in the Salmon River district. This property is under bond to the Algonquin Syndicate of Belgium, represented by W. A. Meloche, a mining engineer who was through the district last summer. Fifty tons of supplies has arrived for the Spider Camp. It is planned to take them over the trail immediately by means of packhorses equipped with snowshoes. Some machinery required for initial development is expected to arrive shortly.

GRAND FORKS.—Active operations are proceeding at the Waterloo mine under the management of G. A. Rendall. A shipment to the Trail smelter consisting of 361 sacks of high-grade silver-lead ore is reported to have been made. Last summer a shipment of 10 tons brought good returns.

MANTOBA

GOLD PAN MINE AT RICE LAKE.

RICE LAKE.—The Gold Pan mine, one of the most prominent enterprises of the Rice Lake district, has so far proved a disappointment and the chances for its making good are not bright. Two reports by engineers who had been engaged to examine the property were recently submitted to the shareholders. The first of these by J. B. Tyrrell was necessarily of a non-conclusive character, as at the time he made his examination the shaft was flooded and he could only examine the surface. He expected to be able to return and complete his work, but was unable to do so and a report was made by R. W. Brigstocke. His conclusion was strongly adverse to any further expenditures on the property. Although the veins contained some rich patches of gold, the quartz outside of these was too low in gold content to be worked at a profit. Moreover the amount even of the low-grade quartz was limited. Notwithstanding the discouraging tenor of the report the shareholders decided on continuing exploration for some months, at the end of which another examination of the property will be made.

ONTARIO

TEMISKAMING REPORT.

COBALT.—During 1919 the Temiskaming mine produced 233,037 oz. of silver with a net value of \$283,623. Costs averaged \$15.61 per ton of ore treated. The surplus for the year amounted to \$70,448, making the total surplus \$993,186. Provision was made for the payment of a

4% dividend in January of this year, and after providing \$29,170 for depreciation the present surplus is \$864,016. In his statement president J. P. Bickell declares the present outlook "does not permit any assurance being given with regard to future dividends". The future policy in this respect depends entirely on developments and the maintenance of the company's sound financial position. Assets are \$3,653,256 as compared with \$3,893,463 a year ago.

Max Morgenthau, minority shareholder in the Buffalo mine, has failed in his application for an injunction restraining the passing of a by-law authorizing the sale of the assets of the Buffalo to the Mining Corporation of Canada for \$462,000. The application was dismissed in the absence of any fraudulent intent being established.

A plan is under way with the object of merging the Adanae property with the Victory Silver Mines. The latter was formerly known as the Hylands property and is situated about 660 ft. south of the Adanae. It is proposed to incorporate a new company with a capitalization of 2,500,000 shares; of this 1,000,000 shares is to go to the Victory and 1,000,000 to the Adanae shareholders, and the remainder to be marketed as a means of financing further work.

PORCUPINE.—No official information as to the operations of the Dome Mines has been forthcoming for some months, and the policy of reticence pursued by the management is unsatisfactory to some of the large shareholders. A party of directors will visit the property before the end of the month, and it is hoped that some definite information will then be made public. As far as can be learned the working force has latterly been somewhat increased and now numbers between 300 and 400 men, the mill continuing to operate at about two-thirds capacity with mill-head running from \$7 to \$9 per ton. The Hollinger Consolidated according to official statements has about 1100 men on the payroll and is treating an average of approximately 2300 tons of ore per day with a recovery of about \$4.77 per ton. Work during the past year was confined to the workings above the 800-ft. level. The program for development includes the establishment of electric haulage-levels at the 650-ft. and 800-ft. levels in addition to that already on the 500-ft. level. At the Clifton-Porcupine electricity will be turned on about March 1. A cross-cut will be run about 800 ft. in length, east and west of present workings on the 200-ft. level to cut eleven veins which have been found to parallel each other. A considerable tonnage of good ore is said to have been blocked out.

KIRKLAND LAKE.—W. Green and associates who have large investments in the camp, have secured an option on a controlling interest in the Montreal-Kirkland. Some good veins are in evidence including one 18 in. wide of \$12 ore. The shaft of the Fidelity has been pumped out and development will be undertaken on the main vein at a vertical depth of 100 ft., where a start had been made when work was stopped by the strike. The vein, 22 in. wide on the surface, had widened to 7 ft. at the bottom of the shaft.

ALASKA

Anchorage.—The Bank of Anchorage is in receipt of advice confirming the sale of the Gold Bullion mine, in the Willow Creek district, to a syndicate of Canadian capitalists, for a consideration of \$500,000. The new owners plan to install an extensive power-plant on the Little Susitna that will not only furnish power for the Gold Bullion, but it is understood will connect with other operating quartz-mines in the district. The Gold Bullion property consists of fourteen claims located on Willow and Craig creeks, in the heart of the famous new quartz camp. Original discovery on the Gold Bullion was made in 1905.

CALIFORNIA

Darwin.—The Darwin Development Co. has resumed work on the Lucky Jim group with 27 men. The shaft is being repaired and arrangements made for further development at depth. Shipping and milling-ore is exposed on the lower levels. Satisfactory development will be followed by the erection of a concentrator and cyanide plant.—The Christmans Gift group, adjoining the Lucky Jim on the south, has passed to the control of the Watterson syndicate, of Bishop, and is being placed in shape for production. The ore contains silver and lead. The Watterson interests have also secured control of the Stevens property. Negotiations are pending with the Tonopah Mining Co. for treatment of the product at Millers, but shipment of the high-grade ore to California and Utah smelters will continue.

Forest.—Sinking on a promising ore-shoot has begun at Kate Hardy mine, where a shaft is being sent to the 200-ft. point. Driving of a tunnel is proceeding with the purpose of reaching the end-lines of the Kate Hardy and Derelict claims. Some good ore has been found. New mine equipment, including an Ingersoll-Rand compressor and Jack-hammer drills, has been purchased. The small mill will be started shortly, and a large plant is planned for erection in the summer.

Keeler.—The Cerro Gordo Mines Co. has resumed work on the Santa Maria group and has opened in a winze a 5-ft. vein of silver-lead-copper ore. Shipments are sent over the five-mile aerial tramline to Keeler, and thence to Utah smelters. Other discoveries have been made recently in the mine.—The Estelle Mining Co. has begun shipments after 20 years of development. An aerial tramline, 7100 ft. long, has been built from the portal of the Morning Star tunnel to the ore-loading station on the Keeler road. The main tunnel, 2200 ft. below the Morning Star lateral, is over 7300 ft. long and penetrates the property at an approximate vertical depth of 3500 ft.—The Santa Rosa Co. reports the opening of a full face of \$50 ore beyond the dike, supposed by former lessees to mark the end of the vein. Shipments are going forward to custom plants.

Lincoln.—The Montezuma Mines Co. has driven a new cross-cut tunnel 880 ft. long and expects to reach the ore-body within 400 ft. Shipments of oxidized ore from the surface workings continue, but the concentrator has been shut down pending completion of the new tunnel.—The Base Metals Co. is sinking a 600-ft. shaft at the Bunker Hill mine to reach a new ore-zone believed to occur at this depth.

Shipping ore continues to be mined from the 150-ft. workings.

Mokelumne Hill.—Grading for the 100-ton mill at Boston mine has been completed and erection of the building begun. Large reserves of ore are blocked out it is said.—Dewatering of the Easy Bird mine has been finished and equipment is arriving. It is understood locally that comprehensive development work will commence shortly.

Shasta County.—The Afterthought Copper Co. has suspended all work on the Afterthought mine and drawn the pumps. It is cleaning up preparatory to closing the reverberatory furnace and the oil-fotation plants. For several months lngot has been the liveliest copper camp in the county. It is not announced how long the present shut-down is likely to last.

IDAHO

Coeur d'Alene.—The Hercules and Tamarack mines, controlled by the Day interests, have started shipping ore to the Bunker Hill smelter at Kellogg. It is rumored that the Days have decided to ship all their ore from their Coeur d'Alene mines to the Bunker Hill, and abandon the Northport plant. Since the strike at the Northport smelter the Bunker Hill company has rushed work in adding to its smelting facilities and it is said that the capacity has been increased 1000 tons per day. This is just about the daily output of the Tamarack and Hercules mines.—A 10-ft. vein has been uncovered in the east drift on the 2000-ft. level of the Hecla mine, according to report. Three feet of the ore is high grade, and the remainder good milling grade, it is said. This ore is on the original Hecla vein and is not involved in the present litigation.

Moscow.—Francis A. Thomson, dean of the school of mines, at the University of Idaho, announces a special conference or post-graduate course for experienced mining men explaining the several phases of the flotation treatment of ores.

Among those who have been assigned places on the program are: Thomas Varley, superintendent of the United States Bureau of Mines at Salt Lake City; C. A. Wright, hydro-metallurgist at the Bureau of Mines station at Salt Lake City; M. S. Sullivan, superintendent of the Bunker Hill smelter; W. L. Ziegler, of Spokane, flotation engineer; and W. L. Penick, of Spokane, metallurgical engineer of the Hardinge Conical Mill Company.

MISSOURI

Webb City.—The new 200-ton mill being erected by T. F. Coyne on the lease he recently procured on the Connor land south-east of Webb City, will be completed and ready for operation within six weeks. The mill will cost about \$30,000. Coyne bought the lease from the Webb City & Carterville Development Co., which was organized as a community drilling project. He paid \$16,000 in cash for the lease, with 15% royalty, which is a 5% increase for the drilling company. Since obtaining the lease two shafts have been sunk, rich lead ore being found at shallow depths.

MONTANA

Butte.—The report of the Butte & Superior Mining Co. for the fourth quarter of 1919 makes possible a survey of

the year's operations. Up to the last of October, the zinc market had been drifting in the same aimless manner it had been pursuing for the past two years. With the advent of winter, however, came a stiffening in price, and the average sales-figure of Butte & Superior for the final quarter was 8½c. per pound, an increase of one cent over the preceding three months.

Net profits for the quarter amounted to \$566,980, equivalent to \$1.95 per share on the 290,184 shares outstanding. This brought the total profits for the year up to \$1,077,493, or \$3.31 per share, 60% of which was contributed by the last three months. These earnings are after taxes and depreciation but before depletion of ore has been provided for.

A very significant and encouraging feature of the last quarterly report was the manner in which the percentage of recovery stood up, notwithstanding the company under Supreme Court mandate was compelled to increase the amount of oil it uses in the flotation process. Average recovery was 93.84% of the zinc in the ore, a decline of but 2% from the preceding 3 months, while the average for the year was 95.6%, an increase of 3% over 1918 and 5% over 1917.

The following table sets forth the salient features of the past three years' operations:

	1919	1918	1917
Tons milled	402,436	468,814	461,953
Average assay zinc, per cent.	14.7	15.9	15.4
Recovery, per cent.	95.6	92.96	91.13
Zinc produced, lb.	113,387,464	138,841,739	131,337,229
Profits per share.	\$3.31	\$2.16	\$6.85
Total costs per ton.	\$9.97	\$11.38	\$9.84

It was understood that the company had \$2,500,000 in net quick assets at the close of 1919, and should the zinc market hold its present firmness it is not improbable that dividends will be resumed regardless of the final accounting to Minerals Separation.

NEW MEXICO

Chino.—At a meeting of the Board of Directors of the Chino Copper Co. a quarterly dividend of 37½c. per share was declared, payable March 31. This will call for a total disbursement of \$326,242. The last quarterly dividend was 75c. per share, which rate was maintained throughout 1919.

WASHINGTON

Danville.—The LeFlour Mountain Copper Co. will resume operations at once, according to W. H. Glunt, formerly of Wallace, who will act as foreman and superintendent. Mr. Glunt says that \$10,000 worth of new machinery has been purchased and that about 12 men will be employed.

MEXICO

The following is quoted from Samuel Montagu & Co. of London:

"The production of silver in Mexico in 1918 was 62,225,344 oz., and the production from January to September 1919 was 46,948,621 oz. It is estimated that the silver production of Mexico for 1919 was about 75,000,000 oz., of which about 3,000,000 was retained in Mexico for coinage, leaving a net export to the United States and elsewhere of 72,000,000 oz. Practically all went to the United States. In addition to the above, it is estimated that about 2,000,000 oz. was exported in the form of coins, which, however, cannot be included in the 1919 production. On November 12, 1919, a decree was issued requiring 50% of the fine silver to be delivered to the Government for coinage, to be paid for on the basis of the New York official price, less shipping expenses and taxes. Owing, however, to the high price of silver, the Government could not afford to continue coining, and since then no more has been taken to the mint. The Government still reserves the right to take 50% of the fine silver produced here. About 40% of the total production is exported as fine silver, the balance in a less concentrated form. The estimated production for 1920 is 80,003,000 ounces."

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Francis Drake writes from Algeria.

Charles Butters is expected in San Francisco on his return from Copala, Mexico.

Henry E. Wood, of Denver, is spending a couple of months at Freeport, Louisiana.

E. Perry Crawford, of Culiacan, Mexico, has returned to Silver City, New Mexico.

C. B. Lakenan, general manager for the Nevada Consolidated Copper Co., is in New York.

Harry Darling, manager of the Porcupine-Crown mine, has returned to Timmins, Ontario.

Blamey Stevens is now with the S. A. de Minas y Montes, at Triunfo, Baja California, Mexico.

E. Shinkai, New York representative of the Furukawa Mining Co., has been in Utah recently.

M. M. Duncan, vice-president and general manager of the Cleveland-Cliffs Iron Co., is in Florida.

Roy B. Earling has joined the staff of the U. S. Smelting, Refining & Mining Co., with headquarters at Boston.

Edwin E. Chase and **R. L. Chase** have moved their offices to 207 Colorado National Bank Bldg., at Denver, Colorado.

C. R. McCollom has returned to private practice at Los Angeles, giving particular attention to the petroleum industry.

Benjamin F. Tibby passed through San Francisco on his way to Los Angeles this week. He is now engaged in the oil industry.

E. H. Dudley and **L. V. Lawhed** have been examining properties near Lordsburg, New Mexico, for the Phelps Dodge Corporation.

R. C. Gosrow has opened an office at 701 Claus Spreckles Bldg., San Francisco, as metallurgical engineer and electro-metallurgist.

P. R. Hines, sales engineer of the mining department of Allis-Chalmers Mfg. Co., passed through San Francisco on his return from Vladivostok.

A. H. Fay has resigned as mining engineer to the U. S. Bureau of Mines, and can be reached at 3224 Oliver St., Chevy Chase, Washington, D. C.

Stephen Royce will have his headquarters at Crystal Falls, Michigan, where he will take care of the interests of the Jackson and Nevada mining companies.

Samuel W. Cohen, general manager for the Bluestone M. & S. Co., at Mason, Nevada, has returned to Montreal, after an examination of the company's property.

D. D. Moffat, consulting engineer of mills for the Jackling copper properties, has returned to Salt Lake City after an inspection of the Ray and Chino concentrating plants.

Alexander Mackay, president of the Dundee-Arizona Copper Co., and his son **F. B. Mackay** of Dundee, Scotland, have been inspecting the company's property at Jerome, Arizona.

T. Kaneda and **A. Sakanonye**, engineers associated with the Nippon Seimi Fertilizer Co., a subsidiary of Furukawa & Co., at Tokyo, have been visiting mining and metallurgical plants in Utah. They are now in New York.

Ray A. Corcoran, mine superintendent for the Santa Gertrudis company, at Pachuca, Mexico, was shot and killed at Pachuca on February 28.

THE METAL MARKET

METAL PRICES

San Francisco, March 2

Aluminum dust, cents per pound.....	12.00
Antimony, cents per pound.....	10.00
Copper, electrolytic, cents per pound.....	10.00

Spelter, cents per pound.....	11.00
Zinc dust, cents per pound.....	12.50-13.00

EASTERN METAL MARKET

(By wire from New York)

March 1—Copper is quiet and easier. Lead is very strong. Zinc is quiet and lower.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46 1/2 pence per ounce (925 fine), calculated at the normal rate of exchange.
